REGULARITY PROPERTIES OF STATIONARY HARMONIC FUNCTIONS WHOSE LAPLACIAN IS A RADON MEASURE

RÉMY RODIAC

Abstract. We study the regularity of Radon measures μ which satisfy that there exists a function h_μ in $H^1(\Omega)$, stationary harmonic such that $\Delta h_\mu = \mu$ in Ω (here Ω is an open set of $\mathbb{R}^2$). Such conditions appear in physical contexts such as the study of a limiting vorticity measure associated to a family $(u_\varepsilon)_\varepsilon$ of solutions of the Ginzburg-Landau system without magnetic field. Under these conditions we prove that locally there exists a harmonic function H such that the support of the measure is contained in the set of zeros of H. Using the local structure of the set of zeros of harmonic functions we can thus obtain that locally the support of μ is a union of smooth simple curves.

1. Introduction and main results

Stationary harmonic functions arise in many physical problems such as the study of Ginzburg-Landau equations linked to superconductivity or the study of Euler equations in fluid mechanics. They are also related to limiting vorticities of stationary system of point vortices. Let Ω be a bounded open set in $\mathbb{R}^2$.

Definition 1.1. *A function h in $H^1(\Omega)$ is stationary harmonic if* $\operatorname{div} T_h = 0$ *in* Ω *in the sense of distributions, where T_h is the stress-energy tensor associated to the Dirichlet energy, defined by*

$$T_h = \begin{pmatrix} \frac{1}{2}\left[(\partial_y h)^2 - (\partial_x h^2)\right] & -\partial_x h \partial_y h \\ -\partial_x h \partial_y h & \frac{1}{2}\left[(\partial_x h)^2 - (\partial_y h^2)\right] \end{pmatrix}. \tag{1}$$

Equivalently h is stationary harmonic in Ω if

$$\omega_h := (\partial_x h)^2 - (\partial_y h)^2 - 2i\partial_x h \partial_y h \text{ is holomorphic in } \Omega. \tag{2}$$

Equation (1) means that $\partial_x (T_h)_{i1} + \partial_y (T_h)_{i2} = 0$ for $i = 1, 2$ in the sense of distributions. Let us denote by $H^{-1}(\Omega)$ the dual of the Sobolev space $H^1_0(\Omega)$. The aim of this paper is to describe the local regularity of Radon measures μ which satisfy the following conditions:

$$\mu \in H^{-1}(\Omega), \tag{3}$$

there exists a function h_μ such that

$$\Delta h_\mu = \mu \text{ in } \Omega, \tag{4}$$

and

$$h_\mu \text{ is stationary harmonic.} \tag{5}$$

Note that if h_μ is a solution of (4) then $h_\mu \in H^1(\Omega)$ and then condition (5) is well-defined. Indeed we can see that there exists a solution of (4) in $H^1_0(\Omega)$ using the

Key words and phrases. Stationary harmonic functions, Radon measure, Ginzburg-Landau system, Euler system, System of point vortices.

Lax-Milgram theorem. Then all the solutions are in $H^1(\Omega)$ since the difference between two solutions is harmonic in Ω end hence belongs to $H^1(\Omega)$.

We will discuss the physical motivations of this problem in the next section. Now we wish to examine in slightly more details the condition (5) and some of its direct consequences. One can show that if h is harmonic ($\Delta h = 0$) then h is stationary harmonic but the converse is not true in general. It is true if h is regular. Indeed using the same techniques as in [11] chapter 13 we can prove that if μ is in L^p for some $p > 1$ then a solution of (3), (4),(5) is harmonic, *i.e.*, $\mu = 0$. For the proof of these facts and other properties of stationary harmonic functions we refer to the Appendix.

Another direct consequence of condition (5) is that $\nabla h_\mu \in L^\infty_{\text{loc}}$ and then h_μ is locally lipschitz continuous. This is due to the fact that $|\nabla h_\mu|^2 = |\omega_{h_\mu}|^2$ and ω_{h_μ} is holomorphic in Ω. In particular h_μ and $|\nabla h_\mu|$ are continuous. The fact that ω_{h_μ} is holomorphic also gives us the following:

Proposition 1.1. *Let h_μ which satisfies that $\omega_{h_\mu} = (\partial_x h_\mu)^2 - (\partial_y h_\mu)^2 - 2i\partial_x h_\mu \partial_y h_\mu$ is holomorphic. Then the zeros of ω_{h_μ} are isolated in Ω. If Ω is compact there is a finite number of such critical points.*

In the present paper we are interested in describing the properties of Radon measures μ which satisfy hypothesis (3), (4), (5). Let us recall that the support of a measure μ is the complement of the largest open set A such that $\mu(A) = 0$. Our first result describes the local regularity of the measure μ in the neighborhood of point z_0 which belongs to the support of μ and such that $\omega_{h_\mu}(z_0) \neq 0$. Note that we can always assume that $h_\mu(z_0) = 0$ because adding a constant to h does not change the hypothesis (3), (4), (5). Note also that near a point z_0 which does not belong to the support of μ the function h_μ is a harmonic function.

Theorem 1.1. *Let $z_0 \in \operatorname{supp}\mu$, with (h_μ, μ) which satisfy assumptions (3), (4), (5) and such that $\omega_{h_\mu}(z_0) \neq 0$. We assume that $h_\mu(z_0) = 0$. Then there exist a neighborhood V of z_0 and a harmonic function H in V such that*

$$h_\mu = |H|, \text{ in } V \text{ or } h_\mu = -|H|, \text{ in } V \tag{6}$$

$$\operatorname{supp}\mu_{\lfloor V} = \{z \in V; H(z) = 0\}. \tag{7}$$

Furthermore we have that $\nabla H(z_0) \neq 0$ and the set $\{z \in V; H(z) = 0\}$ is a smooth simple curve diffeomorphic to a straight line.

Near a point z_0 such that $\omega_{h_\mu}(z_0) = 0$ the behavior of h_μ and the geometry of the support of μ is a little bit more complicated. Nevertheless if z_0 is a zero of even order of ω_{h_μ} the situation is similar.

Theorem 1.2. *Let $z_0 \in \operatorname{supp}\mu$, with (h_μ, μ) which satisfy assumptions (3), (4), (5), and such that z_0 is a zero of even order of ω_{h_μ}. We assume that $h_\mu(z_0) = 0$. Then there exist a neighborhood V of z_0, a harmonic function H in V and a function $\theta : V \to \{\pm 1\}$ such that*

$$h_\mu(z) = \theta(z)H(z) \quad \text{in } V. \tag{8}$$

The function θH is continuous and $\nabla H(z_0) = 0$. Besides the support of $\mu_{\lfloor V}$ is a union of smooth curves included in $\{z \in V; H(z) = 0\}$ which end at z_0.

A key ingredient in the proof of the previous theorem is the local structure of the set of zeros of harmonic functions (see *e.g.* [8] or [12]).

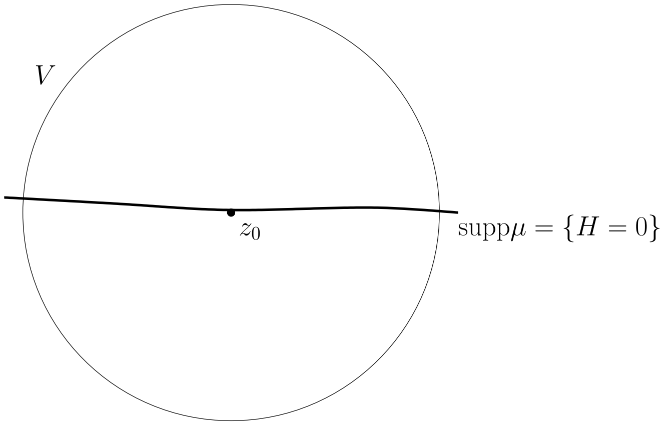

Figure 1. Near a regular point $\operatorname{supp}\mu$ is a smooth curve.

Theorem 1.3 ([12]). *Let H be a harmonic function defined on an open set $D \subset \mathbb{R}^2$. We let $Z_0(H) := \{z \in D; H(z) = 0\}$. Suppose $z_0 \in D$, $H(z_0) = 0$ and H is not identically zero. Then there exist a unique integer $n = n(H, z_0) \geq 1$, a neighborhood $U(z_0)$ of z_0 in D and n analytic curves*

$$\gamma_k :]-1,1[\to U(z_0), \qquad (k = 1, 2, ..., n)$$

such that $\gamma_k(0) = z_0$ and:

1) *$Z_0(H) \cap U(z_0) = \cup_{k=1}^{n} \gamma_k$ (where γ_k denotes the set $\{\gamma_k(t); t \in]-1,1[\}$)*
2) *$\operatorname{ang}(\gamma_k, \gamma_{k+1}) = \frac{\pi}{n}$, $k = 1, ..n$, where γ_{n+1} denotes γ_1 and $\operatorname{ang}(\gamma_k, \gamma_{k+1})$ is the angle between γ_k and γ_{k+1} at z_0.*
3) *There exists an analytic diffeomorphism $\phi : U(z_0) \to B(0, 1)$ such that*
$$\phi \circ \gamma_k(t) = t \exp(i\theta_k)$$
where $t \in]-1,1[$, $k = 1, ..., n, \theta_k = \frac{\pi}{2n} + \frac{(k-1)\pi}{n}$.

This means that $\Gamma_k = \phi(\gamma_k)$ are n symmetrically placed diameters of $B(0, 1)$.

Remark: Note that in Theorem 1.2 it can happen that the support of μ is strictly contained in the set $\{z \in v; H(z) = 0\}$. In this case we can not have $h_\mu = |H|$. This is illustrated by the following example: we set $h(re^{i\varphi}) = \theta(\varphi) r^2 \cos(2\varphi)$, for $r \in [0, 1]$, $\varphi \in [0, 2\pi[$ and

$$\theta(\varphi) = \begin{cases} -1, & \text{if } \frac{\pi}{4} \leq \varphi \leq \frac{3\pi}{4} \\ +1, & \text{otherwise.} \end{cases}$$

This function h satisfies (3), (4), (5). In particular one can check that $\Delta h = \mu$ with $\text{supp}(\mu) = D_1 \cup D_2$ where $D_1 = \{z = re^{i\varphi}, 0 \leq r \leq 1 \text{ and } \varphi = \frac{\pi}{4}\}$, $D_2 = \{z = re^{i\varphi}, 0 \leq r \leq 1 \text{ and } \varphi = \frac{3\pi}{4}\}$

When $z_0 \in \text{supp}(\mu)$ is a zero of odd order of ω_{h_μ} we must use multivalued harmonic function.

Theorem 1.4. *Let $z_0 \in \operatorname{supp}\mu$ with (h_μ, μ) which satisfy assumptions (3), (4), (5), and such that z_0 is a zero of odd order of ω_{h_μ}. We assume that $h_\mu(z_0) = 0$. Then there exist a neighborhood V of z_0, a multivalued harmonic function H_1 in V such that $H := |H_1|$ is a single-valued function and a function $\theta : V \to \{\pm 1\}$ such that*

$$h_\mu(x) = \theta(x) H(x) \quad \text{in } V, \tag{9}$$

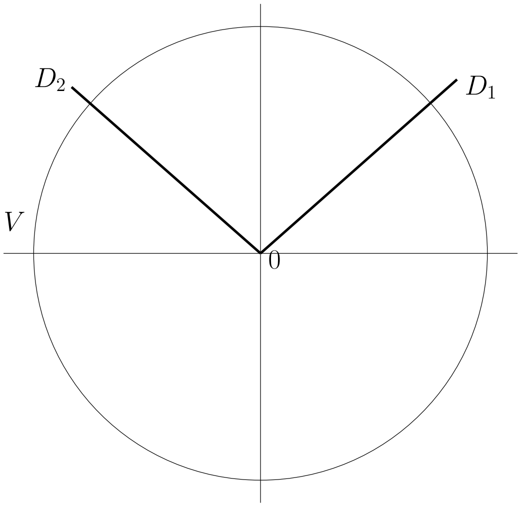

FIGURE 2. An example of the geometry of supp μ near a critical point of h_μ.

the function θH being continuous and $\nabla H(z_0) = 0$. Besides the support of $\mu_{\lfloor V}$ is a union of smooth curves included in $\{z \in V; H(z) = 0\}$ which end at z_0.

Furthermore the function H_1 is such that: there exist an unique integer $n \geq 1$, a small number $r > 0$ and a biholomorphism $\Phi : B(0,r) \to V$ such that $\Phi(0) = z_0$ and

$$H_1 \circ \Phi(z) = Re(z^{n+\frac{1}{2}}), \quad \textit{for } z \in B(0,r) \tag{10}$$

Thanks to the property satisfied by the function H_1 in the previous theorem we can obtain a description of the set of zeros of H_1 similar to Theorem 1.3.

Theorem 1.5. *let H_1 be as in the previous Theorem 1.4. Then there exist $2n+1$ analytic curves*

$$\gamma_k :]-1,1[\to V, \quad (k = 1, 2, ..., 2n+1)$$

such that $\gamma_k(0) = z_0$ and

1) $\{z \in \mathbb{R}^2; H_1(z) = 0\} \cap V = \cup_{k=1}^{2n+1} \gamma_k$
2) $\text{ang}(\gamma_k, \gamma_{k+1}) = \frac{2\pi}{n+1}$, $k = 1, ..., 2n+1$, *where γ_{2n+n} denotes γ_1 and* $\text{ang}(\gamma_k, \gamma_{k+1})$ *is the angle between γ_k and γ_{k+1} at z_0.*
3) *There exists an analytic diffeomorphism $\phi : V \to B(0,1)$ such that*

$$\phi \circ \gamma_k(t) = t \exp(i\theta_k)$$

where $t \in]-1,1[$, $k = 1, ..., 2n+1$, and $\theta_k = \frac{\pi}{2n+1} + \frac{2(k-1)\pi}{2n}$.

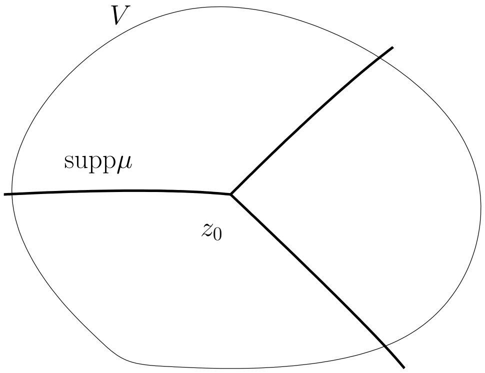

FIGURE 3. Illustration of Theorem 1.4.

In order to conclude this introduction we would like to comment on the hypothesis (3), (4), (5). First note that the fact that h_μ is in H^1 (or equivalently that $\mu \in H^{-1}$) is essential to assume (5) since we take the divergence of the tensor T_μ in the sense of distributions we must have that its coefficients are in L^1_{loc}. Then we want to give an example which shows that (5) does not necessarily imply that μ is a Radon measure. The example is the following: one can take h defined on $[0,1]$ such that $h(0)=0$ and

$$h'(x) = \begin{cases} +1, & \text{if } x \in]\frac{1}{n+1}, \frac{1}{n}[\text{ with } n \text{ even} \\ -1, & \text{if } x \in]\frac{1}{n+1}, \frac{1}{n}[\text{ with } n \text{ odd.} \end{cases}$$

We then have that $h \in H^1([0,1])$, and h satisfies $\omega_h = |h'(x)|^2 = 1$ is holomorphic. But $\Delta h = \sum_{n=2}^{+\infty} \delta_{\frac{1}{n}}$ is not a Radon measure.

The paper is organized as follows: In Section 2 we explain the physical motivations for studying this problem. Section 3 is devoted to the description of the measure μ near a point z_0 such that $\omega_{h_\mu}(z_0) \neq 0$. In Section 4 we discuss the case of a zero of even order of ω_{h_μ} and in Section 5 the case of a zero of odd order of ω_{h_μ}.

2. Physical motivations of the problem

2.1. **Connections to Ginzburg-Landau vortices without magnetic field.** The conditions (3), (4), (5) are motivated by the problem of describing limiting vorticities for the critical points $(u_\varepsilon)_\varepsilon$ of the Ginzburg-Landau energy without magnetic field

$$E_\varepsilon(u) = \frac{1}{2}\int_\Omega |\nabla u|^2 dx + \frac{1}{4\varepsilon^2}\int_\Omega (1-|u|^2)^2 dx. \tag{11}$$

Here u is a complex-valued function called the *order parameter* and its isolated zeros are called *vortices*. The Ginzburg-Landau theory is a model for describing the superconductivity. The Ginzburg-Landau system without magnetic field was studied by Béthuel-Brézis-Hélein in [3]. Later on Sandier-Serfaty in [11] studied the Ginzburg-Landau system with magnetic field which is a more physically relevant model. The vortices are important features of the model. They correspond to small regions in the superconducting sample where the superconductivity is destroyed. Let Ω be a bounded domain in $\mathbb{R}^2$. We consider a family $(u_\varepsilon)_{\varepsilon>0}$ of solutions of

$$-\Delta u_\varepsilon = \frac{u_\varepsilon}{\varepsilon^2}(1-|u_\varepsilon|^2) \text{ in } \Omega. \tag{12}$$

We assume that $|u_\varepsilon| \leq 1$ in Ω and

$$E_\varepsilon(u_\varepsilon) < C_0 \varepsilon^{\alpha-1}, \ \alpha > \frac{2}{3} \tag{13}$$

for every $\varepsilon > 0$. We let $j_\varepsilon = \langle iu_\varepsilon, \nabla u_\varepsilon\rangle$ where $\langle .,. \rangle$ denotes the inner product in $\mathbb{C}$ identified with $\mathbb{R}^2$. We also let $\mu_\varepsilon = \operatorname{curl} j_\varepsilon$. Here j_ε describes superconducting currents and μ_ε is the vorticity of these currents. A direct calculation shows that $\operatorname{div} j_\varepsilon = 0$ hence we can write $j_\varepsilon = \nabla^\perp h_\varepsilon$ for some function h_ε. Furthermore this function satisfies the following equation

$$\left\{ \begin{array}{rcl} \Delta h_\varepsilon &=& \mu_\varepsilon \text{ in } \Omega \\ \partial_\nu h_\varepsilon &=& \langle j_\varepsilon, \tau\rangle \text{ on } \partial\Omega. \end{array} \right. \tag{14}$$

Here ν is the outward pointing normal to $\partial\Omega$ and $\tau = \nu^\perp$. By the solution to (14) we mean the solution with zero average in Ω. We split h_ε into two pieces: let us define h^0_ε

and h^1_ε by

$$\left\{ \begin{array}{rcl} -\Delta h^1_\varepsilon & = & \mu_\varepsilon \text{ in } \Omega, \\ h^1_\varepsilon & = & 0 \text{ on } \partial\Omega. \end{array} \right. , \quad h^0_\varepsilon = h_\varepsilon - h^1_\varepsilon.$$

We recall the following result which describes the behavior of the vorticity measure as ε goes to 0 (see [10] and [11]).

Theorem 2.1 (Theorem 13.2 in [11]). A) *Let $\{u_\varepsilon\}_{\varepsilon>0}$ be solutions of* (12). *Then for any $\varepsilon > 0$, there exists a measure ν_ε of the form $2\pi \sum_i d^\varepsilon_i \delta_{a^\varepsilon_i}$ where the sum is finite, $a^\varepsilon_i \in \Omega$ and $d^\varepsilon_i \in \mathbb{Z}$ for every i, such that, letting $n_\varepsilon = \sum_i |d^\varepsilon_i|$,*

$$n_\varepsilon \leq C \frac{E_\varepsilon(u_\varepsilon, \mathcal{B}_\varepsilon)}{|\log \varepsilon|}, \tag{15}$$

where $\mathcal{B}_\varepsilon$ is a union of balls of total radius less than $C\varepsilon^{2/3}$, and such that

$$\|\mu_\varepsilon - \nu_\varepsilon\|_{W^{-1,p}(\Omega)} \|\mu_\varepsilon - \nu_\varepsilon\|_{(C^0(\Omega))^*} \to 0, \tag{16}$$

for some $p \in (1,2)$.

B) *Let $\{\nu_\varepsilon\}_\varepsilon$ be any measures of the form $2\pi \sum_i d^\varepsilon_i \delta_{a^\varepsilon_i}$ satisfying* (16), *let $n_\varepsilon = \sum_i |d^\varepsilon_i|$, and let $\{M_\varepsilon\}_\varepsilon$ be positive real numbers such that $\{h^0_\varepsilon / M_\varepsilon\}_\varepsilon$ converges in $L^1_{loc}(\Omega)$ to a function H_0. Then H_0 is harmonic and, possibly after extraction, one of the following holds.*

0) *$n_\varepsilon = 0$ for every ε small enough and then μ_ε tends to 0 in $W^{-1,p}(\Omega)$.*
1) *$n_\varepsilon = o(M_\varepsilon)$ is nonzero for ε small enough, and then $\mu_\varepsilon / n_\varepsilon$ converges in $W^{-1,p}(\Omega)$ to a measure μ such that*

$$\mu \nabla H_0 = 0,$$

hence the support of μ is contained in the set of critical points of H_0.

2) *$M_\varepsilon \sim \lambda n_\varepsilon$, with $\lambda > 0$, and then $\mu_\varepsilon / M_\varepsilon$ converges in $W^{-1,p}(\Omega)$ to a measure μ, and $h_\varepsilon / M_\varepsilon$ converges in $W^{1,p}_{loc}(\Omega)$ to a solution of $\Delta h_\mu = \mu$ in Ω. Moreover the symmetric 2-tensor T_μ with coefficients T_{ij} given by*

$$T_{ij} = -\partial_i h_\mu \partial_j h_\mu + \frac{1}{2} |\nabla h_\mu|^2 \delta_{ij} \tag{17}$$

is divergence-free in finite part (see Definition 2.1 below).

3) *$M_\varepsilon = 0(n_\varepsilon)$, and then $\mu_\varepsilon / n_\varepsilon$ converges in $W^{-1,p}(\Omega)$ to a measure μ, and $h_\varepsilon / n_\varepsilon$ converges in $W^{1,p}_{loc}(\Omega)$ to the solution of*

$$\left\{ \begin{array}{rcl} \Delta h_\mu & = & \mu \text{ in } \Omega \\ h_\mu & = & 0 \text{ on } \partial\Omega. \end{array} \right. \tag{18}$$

Moreover the symmetric 2-tensor T_μ with coefficients T_{ij} given by (17) *is divergence-free in finite part.*

In cases 2) and 3), if $\mu \in H^{-1}(\Omega)$ then solutions of $\Delta h_\mu = \mu$ are in $H^1_{loc}(\Omega)$. Thus T_μ is in $L^1_{loc}(\Omega)$ and we have that $\operatorname{div}(T_\mu) = 0$ *in the sense of distributions. In other words h_μ is stationary harmonic.*

Hence we can see that the limiting vorticity in cases 2), 3), with the additional hypothesis that $\mu \in H^{-1}(\Omega)$ satisfies condition (4), (5). Understanding the limiting measure μ will in turn give qualitative information on the behavior of vortices.
We now recall the definition of the notion of divergence-free in finite part taken from [11].

Definition 2.1. *Assume X is a vector field in Ω. We say that X is divergence-free in finite part if there exists a family of sets $\{E_\delta\}_{\delta>0}$ such that*

1. *For any compact $K \subset \Omega$, we have* $\lim_{\delta\to 0} \operatorname{cap}_1(K \cap E_\delta) = 0$.

2. *For every* $\delta > 0$, $X \in L^1(\Omega \setminus E_\delta)$.
3. *For every* $\zeta \in C_c^\infty(\Omega)$,
$$\int_{\Omega \setminus F_\delta} X \cdot \nabla\zeta = 0$$
where $F_\delta = \zeta^{-1}(\zeta(E_\delta))$. *If* T *is a 2-tensor with coefficients* $\{T_{ij}\}_{1\le i,j\le 2}$, *we say that* T *is divergence free in finite part if the vectors* $T_i = (T_{i1}, T_{i2})$ *are, for* $i = 1, 2$.

In this definition we denoted by cap_1 the 1-capacity of a set $E \subset \mathbb{R}^2$ and we recall from Evans-Gariepy [6] that the p-capacity $(1 \le p < 2)$ of a set E is defined as

$$\mathrm{cap}_p(E) = \inf\{\int_{\mathbb{R}^2} |\nabla\varphi|^p; \varphi \in L^{p^*}(\mathbb{R}^2), \nabla\varphi \in L^p(\mathbb{R}^2), A \subset int(\varphi \ge 1)\},$$

where $int(A)$ denotes the interior of A and $p^* = \frac{2p}{2-p}$. We would like mention that in [9], the author studied limiting vorticity measures associated to the Ginzburg-Landau system with magnetic field. This leads to conditions analog to (3), (4), (5). He investigated these conditions under the additional assumption that the measure μ is supported by a simple smooth curve. He then proved, among other things, that in that in this case μ has a fixed sign.

2.2. **Connections to the Euler System.** It turns out that conditions (4), (5) are also related to the Euler equations for incompressible flow in fluid mechanics. They can be written as follows:

$$\left\{\begin{array}{rcl} \partial_t v + (v\cdot\nabla)v + \nabla p &=& 0 \text{ in } \Omega \\ \mathrm{div}(v) &=& 0 \text{ in } \Omega \end{array}\right. \tag{19}$$

where Ω is an open set of $\mathbb{R}^2$. In this system p is called the pressure and it is an unknown of the system. Here $v\cdot\nabla v := v_1\partial_x v + v_2\partial_y v$, and v is the velocity of the fluid. The system is stationary if it does not involve in time, *i.e.*, if $\partial_t v = 0$ in Ω. A quantity of particular interest in fluid mechanics is the vorticity of the fluid defined by

$$\mu = \mathrm{curl}\, v. \tag{20}$$

We must be more specific to define the notion of solutions of the Euler system. Indeed we want to give a meaning to (19) for vector-fields which are only in $L^2(\Omega)$. First note that thanks to the condition $\mathrm{div}(v) = 0$ we can rewrite the stationary Euler system in the following form:

$$\left\{\begin{array}{rcl} \mathrm{div}(v\otimes v) + \nabla p &=& 0 \\ \mathrm{div}(v) &=& 0. \end{array}\right. \tag{21}$$

where $(v\otimes v)$ is a 2×2 matrix given by $(v\otimes v)_{i,j} = v_i v_j$, for $1 \ge i, j \ge 2$. The divergence of a matrix is the sum of the divergence of the row. Let us denote by $\langle A, B\rangle := \mathrm{tr}(A^t B)$ the inner product between two matrices.

Definition 2.2. *Let* Ω *be an open set in* $\mathbb{R}^2$. *We say that* $v \in L^2(\Omega, \mathbb{R}^2)$ *is a weak solution of* (21) *if there exists* $p \in L^1(\Omega)$ *such that*

$$\int_\Omega \langle v\otimes v, D\varphi\rangle + \int_\Omega p\,\mathrm{div}(\varphi) = 0, \quad \forall\ \varphi \in \mathcal{C}_c^\infty(\Omega, \mathbb{R}^2). \tag{22}$$

Proposition 2.1. *Let* h_μ *satisfy* (3), (4), (5). *We set* $v = \nabla^\perp h_\mu$. *Then* v *is a weak solution of the stationary Euler system with vorticity equal to* μ.

Proof. Let $\varphi=(\varphi_1,\varphi_2)\in\mathcal{C}_c^\infty(\Omega,\mathbb{R}^2)$, recall that $\nabla^\perp h=(-\partial_y h,\partial_x h)$.

$$\int_\Omega\langle\nabla^\perp h\otimes\nabla^\perp h,D\varphi\rangle=\int_\Omega(\partial_y h)^2\partial_x\varphi_1-(\partial_y h\partial_x h)\left[\partial_y\varphi_1+\partial_x\varphi_2\right]+(\partial_x h)^2\partial_y\varphi_2.$$

However because of the condition (5) we have

$$\begin{aligned}\int_\Omega\frac{1}{2}(\partial_y h^2-\partial_x h^2)\partial_x\varphi_1-(\partial_x h\partial_y h)\partial_y\varphi_1&=0\\ \int_\Omega(-\partial_x h\partial_y h)\partial_x\varphi_2+\frac{1}{2}(\partial_x h^2-\partial_y h^2)\partial_y\varphi_2&=0.\end{aligned}$$

Hence we can rewrite

$$\int_\Omega\langle\nabla^\perp h\otimes\nabla^\perp h,D\varphi\rangle=\int_\Omega\frac{1}{2}(\partial_x h^2+\partial_y h^2)\partial_x\varphi_1+\int_\Omega\frac{1}{2}(\partial_x h^2+\partial_y h^2)\partial_y\varphi_2.$$

We then set $p=\frac{1}{2}|\nabla h|^2\in L^1(\Omega)$ and we obtain that for all $\varphi\in\mathcal{C}_c^\infty(\Omega,\mathbb{R}^2)$ we have

$$\int_\Omega\langle\nabla^\perp h\otimes\nabla^\perp h,D\varphi\rangle=-\int_\Omega p\operatorname{div}(\varphi).$$

Thus $v=\nabla^\perp h$ is a weak solution of stationary Euler system, with pressure $p=\frac{1}{2}|\nabla h|^2$ and with vorticity equal to $\operatorname{curl}\nabla^\perp h=\Delta h=\mu$. □

The previous Proposition 2.1 combined with Theorems 1.1, 1.2, 1.4, implies that if v is a weak solution of the Euler system (21) such that $v=\nabla^\perp h$ with h which satisfies hypothesis (3), (4), (5) then v is a *vortex sheet* solution of (21). The vortex sheet problem consists in finding a solution (v,p) of (19) such that the initial data $v_{|t=0}=v_0$ satisfies that $\operatorname{div}(v_0)=0$ and $\omega_0=\operatorname{curl}v_0=\delta_\Sigma$ with Σ a compact smooth curve in $\mathbb{R}^2$. The existence of global solution of vortex sheet solutions of the Euler equation is due to J.M Delort in [5]. Note that in his paper an important assumption for the proof of the existence of global solution of vortex sheet solutions is that the initial data $\omega_0=\operatorname{curl}v_0=\mu$ is a positive (or negative) measure. However in cases of theorems 1.2, 1.4, it can happen that μ has no sign. For example setting $h(r,\varphi)=\theta(\varphi)r^2\cos(2\varphi)$ with $\theta(\varphi)=+1$, if $-\frac{3\pi}{4}\le\varphi\le\frac{\pi}{4}$ and $\theta(\varphi)=-1$ if $\varphi\in[-\pi,\pi]\setminus[-\frac{3\pi}{4},\frac{\pi}{4}]$. Then one can check that Δh is a measure with no fixed sign.

Let us mention that not all stationary solutions of the Euler system (21) can be written as $v=\nabla^\perp h$ with h which satisfies (3),(4),(5). For example we take $v=(-y,x)$ for $x,y\in B(0,1)$. Then we can check that v is a solution of (21) with $p=\frac{1}{2}(x^2+y^2)$. We can write $v=\nabla^\perp h$ with $h=\frac{1}{2}(x^2+y^2)$. But h satisfies that $\omega_h=(x-iy)^2$ and it is not holomorphic. Hence (5) is not satisfied. Note that in this case $\Delta h=1$ in $B(0,1)$. Such a solution is called a *vortex patch*.

2.3. Connections to system of point vortices.

A system of N-point vortices in evolution is described by the following system of ordinary differential equations

$$\frac{dz_i}{dt}(t)=\nabla^\perp\left[\sum_{j=1,j\neq i}^N d_j\ln|z-z_j(t)|\right](z_i(t)),\ \forall i=1,...,N. \tag{23}$$

with $\nabla^\perp=(-\partial_y,\partial_x)$ and $d_j\in\mathbb{N}$. The points $z_i(t)$ are called vortices and d_i are the *degrees* of vortices. The system is *stationary* if the vortices do not evolve in time, one then has

$$\sum_{j=1, j\neq i}^{N} d_j \frac{z_i - z_j}{|z_i - z_j|^2} = 0, \quad \forall i = 1, ..., N. \tag{24}$$

A natural question is the following: *What are the limiting vorticities of a stationary system of point vortices when the number of points tends to infinity?*

Let us reformulate precisely this question. Let Ω be a bounded domain, we are interested in Radon measure μ which satisfies the following conditions:

$$\forall \varepsilon > 0, \exists N^{\varepsilon} \in \mathbb{N},\ (z_i^{\varepsilon})_{1\leq i\leq N_{\varepsilon}} \in \Omega,\ d_i^{\varepsilon} \in \mathbb{Z}\ \text{ s.t.} \|\mu - 2\pi \sum_{i=1}^{N^{\varepsilon}} d_i^{\varepsilon} \delta_{z_i^{\varepsilon}} \|_{(\mathcal{C}^0(\Omega))^*} < \varepsilon \tag{25}$$

$$\big((z_i^{\varepsilon})_{1\leq i\leq N_{\varepsilon}}, (d_i^{\varepsilon})_{1\leq i\leq N^{\varepsilon}}\big) \text{ define a stationary system of point vortices.} \tag{26}$$

The limiting vorticities of a stationary system of point vortices are described by a result analog to Theorem 2.1:

Theorem 2.2. *Let Ω be a bounded domain. Let μ be a Radon measure in Ω which satisfies* (25) *and* (26)*. There exists a function $u \in L^1_{loc}(\Omega)$ such that*

1) $\Delta u = \mu$

2) *The tensor*

$$T_u = \begin{pmatrix} \frac{1}{2}\left[(\partial_y u)^2 - (\partial_x u)^2\right] & -\partial_x u \partial_y u \\ -\partial_x u \partial_y u & \frac{1}{2}\left[(\partial_x u)^2 - (\partial_y u)^2\right] \end{pmatrix}$$

is divergence-free in finite parts. Furthermore if μ is in $H^{-1}(\Omega)$ then u is in $H^1(\Omega)$ and $\operatorname{div}(T_u) = 0$ in the sense of distributions. That is u satisfies the conditions (3)*,* (4)*,* (5)*.*

Thanks to the previous theorem we see that studying the conditions (3), (4), (5) can be useful to obtain information about the vorticity of a stationary system of point vortices when the number of vortices tends to infinity. The rest of this subsection is devoted to the definitions needed in the statement of Theorem 2.2 and its proof. The definitions and some results are taken from [11] Chapter 13.

In this section we use an equivalent definition of divergence-free in finite part:

Definition 2.3. *Let X be a vector field in Ω, and $z_1, ... z_N$ in Ω such that $X \in C^0(\Omega \setminus \{z_1, ..., z_N\})$. We say that X is divergence free in finite part if*

1. $\operatorname{div}(X) = 0$ *in* $\mathcal{D}'(\Omega \setminus \{z_1, ..., z_N\})$.
2. $\int_{\partial B(z_i,\delta)} X.\nu_i = 0$, $\forall\ i = 1, ..., N$, $\forall \delta > 0$ *where ν denotes the outward unit normal to $\partial B(z_i, \delta)$.*

The equivalence between the two previous definitions can be proved using the coarea formula.

Definition 2.4. *We say that u is weakly stationary harmonic if T_u is divergence free in finite part.*

Example 2.1. *$u(z) = \ln|z|$ is weakly stationary harmonic in $\mathbb{R}^2$.*

Proof. Let $z = x + iy$. We have that $\ln|z|$ is harmonic in $\mathbb{R}^2 \setminus \{0\}$ and smooth in $\mathbb{R}^2 \setminus \{0\}$. Then it is stationary harmonic in $\mathbb{R}^2 \setminus \{0\}$, that is $\operatorname{div}(T_u) = 0$ in $\mathbb{R}^2 \setminus \{0\}$, with $T_u = \begin{pmatrix} \partial_x u^2 - \partial_y u^2 & 2\partial_x u \partial_y u \\ 2\partial_x u \partial_y u & \partial_y u^2 - \partial_x u^2 \end{pmatrix}$. We want to show the second condition in the previous definition. Let $\delta > 0$ we have

$$\partial_x u^2 - \partial_y u^2 = \frac{x^2 - y^2}{|z|^2} \text{ and } 2\partial_x u \partial_y u = \frac{xy}{|z|^2}.$$

The outward unit normal to $\partial B(0,\delta)$ is $\nu = \frac{z}{|z|}$. Hence, for all $\delta > 0$ small:

$$\begin{aligned} \int_{\partial B(0,\delta)} (\partial_x u^2 - \partial_y u^2)\nu_1 + (2\partial_x u \partial_y u)\nu_2 &= \int_{\partial B(0,\delta)} \frac{x(x^2+y^2)}{|z|^3} \\ &= \delta \int_0^{2\pi} \cos(\varphi) d\varphi = 0. \end{aligned}$$

The integral of the other component of T_h is computed the same way and we also find that it is equal to 0. Thus u is weaky stationary harmonic. □

We can associate to a system of point vortices (24) the measure $\sum_{i=1}^N d_i \delta_{z_i}$, where we denoted by δ_{z_0} the Dirac mass in z_0. Let us consider the particular solution of

$$\Delta u = \frac{2\pi}{M_N} \sum_{i=1}^N d_i \delta_{z_i} \tag{27}$$

given by

$$u(z) = \frac{1}{M_N} \sum_{i=1}^N d_i \ln|z - z_i|, \text{ where } M_N = \sum_{i=1}^N |d_i|. \tag{28}$$

Proposition 2.2. *The points $(z_i)_{1 \le i \le N} \in \mathbb{R}^2$ form a stationary system of point vortices if and only if the function $u(z) = \frac{1}{M_N}\sum_{i=1}^N d_i \ln|z - z_i|$ is weakly stationary harmonic.*

Remark: Note that if u is not in $H^1(\Omega)$ then it does not make sense to say that u is stationary harmonic that is why we need the notion of weak stationary harmonicity.

Proof. We use Definition 2.3. Again away from the points $z_1, ..., z_N$, u is harmonic and smooth. Thus it is stationary harmonic. Near z_1 we have

$$u(z) = \alpha_1 \ln|z - z_1| + H_1(z)$$

where $H_1(z) := \frac{1}{M_N}\sum_{i=2}^N d_i \ln|z - z_i|$ is harmonic near z_1 (in a neighborhood of z_1 which contains only z_1 and no other z_i) and α_1 is a constant. Without loss of generality we can assume that $\alpha_1 = 1$ and $z_1 = 0$. We then have:

$$\begin{aligned} \partial_x u^2 - \partial_y u^2 &= \left(\frac{x}{|z|} + \partial_x H_1(z)\right)^2 - \left(\frac{y}{|z|} + \partial_y H_1(z)\right)^2 \\ &= \frac{x^2 - y^2}{|z|^2} + (\partial_x H_1^2 - \partial_y H_1^2) + 2\left(\frac{x}{|z|}\partial_x H_1 - \frac{y}{|z|}\partial_y H_1\right) \end{aligned}$$

$$2\partial_x u \partial_y u = 2\frac{xy}{|z|^2} + 2\partial_x H_1 \partial_y H_1 + 2\left(\frac{x}{|z|}\partial_y H_1 + \frac{y}{|z|}\partial_x H_1\right)$$

Thus

$$\begin{aligned}\int_{\partial B(0,\delta)} (\partial_x u^2 - \partial_y u^2)\nu_1 + (2\partial_x u \partial_y u)\nu_2 &= \int_{\partial B(0,\delta)} \frac{x^2-y^2}{|z|^2}\nu_1 + 2\frac{xy}{|z|^2}\nu_2 \\ &+ \int_{\partial B(0,\delta)} (\partial_x H_1^2 - \partial_y H_1^2)\nu_1 + (2\partial_x H_1 \partial_y H_1)\nu_2 \\ + \int_{\partial B(0,\delta)} 2\left(\frac{x}{|z|}\partial_x H_1 - \frac{y}{|z|}\partial_y H_1\right)\nu_1 &+ 2\left(\frac{x}{|z|}\partial_y H_1 + \frac{y}{|z|}\partial_x H_1\right)\nu_2.\end{aligned}$$

The first term in this sum is zero because $\ln|z|$ is weakly stationary harmonic. The second term is also zero because H is harmonic, smooth, and hence stationary harmonic and weakly stationary harmonic. For the third term we can use the fact that the normal on $\partial B(0,\delta)$ is $\nu = \frac{z-z_1}{|z-z_1|}$ to prove that it is equal to $2\int_{\partial B(0,\delta)} \partial_x H_1$.

Hence if u is weakly stationary harmonic this term must be equal to zero for all δ. Then dividing this quantity by δ and letting δ go to 0 we find that $\partial_x H_1(z_1) = 0$. With the same method applied to the other component of T_u we obtain

$$\int_{\partial B(0,\delta)} (2\partial_x u \partial_y u)\nu_1 + (\partial_y u^2 - \partial_x u^2)\nu_2 = 2\int_{\partial B(0,\delta)} \partial_y H_1.$$

Thus if u is weakly stationary harmonic we find that $\nabla H_1(0) = 0$. By repeating this argument near each z_i, we obtain that if u is weakly stationary harmonic then $z_1, ..., z_N$ form a stationary system of point vortices:

$$\sum_{j=1, j\neq i}^{N} d_j \frac{z_i - z_j}{|z_i - z_j|^2} = 0 \ \forall i = 1, ..., N.$$

□

We now prove Theorem 2.2. Let μ be a Radon measure which satisfies (25), (26). We set

$$u_{N^\varepsilon} := \frac{1}{M_{N^\varepsilon}} \sum_{i=1}^{N} d_i^\varepsilon \ln|z - z_i^\varepsilon| \tag{29}$$

with $M_{N^\varepsilon} = \sum_{i=1}^{N^\varepsilon} |d_i^\varepsilon|$. We want to prove that u_{N^ε} converges to a function u when ε goes to 0 such that u satisfies $\Delta u = \mu$ and u is weakly stationary harmonic. However we need to have a notion of convergence which preserves the notion of weak stationary harmonicity. This is the object of the following definition.

Definition 2.5 ([11]). *We say (with some abuse of notation) that a sequence $(X_n)_n$ in $L^1(\Omega)$ converges in $L^1_\delta(\Omega)$ to X if $X_n \to X$ in $L^1_{loc}(\Omega)$ except on a set of arbitrarily small 1-capacity, or precisely if there exists a family of sets $(E_\delta)_{\delta>0}$ such that for any compact $K \subset \Omega$,*

$$\lim_{\delta\to 0} \operatorname{cap}_1(K \cap E_\delta) = 0, \quad \text{and } \forall \delta > 0 \ \lim_{n\to+\infty} \int_{K\setminus E_\delta} |X_n - X| = 0. \tag{30}$$

We define similarly the convergence in L^2_δ by replacing L^1 by L^2 in the above.

Proposition 2.3 ([11]). *Assume $(X_n)_{n\in\mathbb{N}}$ is a sequence of divergence-free in finite part vector fields which converges to X in $L^1_\delta(\Omega)$. Then X is divergence free in finite part.*

Corollary 2.1. *Assume that u_N is a sequence of weakly stationary harmonic functions such that u_N converges to u in $L^2_\delta(\Omega)$ and ∇u_N converges in $L^2_\delta(\Omega)$ then u is weakly stationary harmonic.*

Thus to prove Theorem 2.2 we only need to prove that the functions u_{N^ε} converge in $L^2_\delta(\Omega)$ to a function u such that ∇u_{N^ε} converge to ∇u in $L^2_\delta(\Omega)$.

Proposition 2.4. *Let Ω be a bounded open set in $\mathbb{R}^2$. Let μ be a Radon measure in Ω such that (25),(26) hold. Let $u_{N^\varepsilon} = \frac{1}{M_{N^\varepsilon}} \sum_{i=1}^N d_i^\varepsilon \ln|z - z_i^\varepsilon|$ then there exists u such that u_{N^ε} converge in $L^2_\delta(\Omega)$ to u and ∇u_{N^ε} converge to ∇u in $L^2_\delta(\Omega)$.*

Proof. We let

$$\mu_{N^\varepsilon} := \frac{2\pi}{M_{N^\varepsilon}} \sum_{i=1}^{N^\varepsilon} \delta_{z_i^\varepsilon}. \tag{31}$$

Since Ω is bounded the measure μ_{N^ε} has compact support and we can then write

$$u_{N^\varepsilon} = \ln|z| * \mu_{N^\varepsilon} \tag{32}$$

where $*$ denotes the convolution product. Then for all φ in $\mathcal{C}_c^\infty(\mathbb{R}^2)$ we have

$$\langle u_{N^\varepsilon}, \varphi\rangle = \langle \ln|z| * \mu_{N^\varepsilon}, \varphi\rangle = \langle \mu_{N^\varepsilon}, \ln|z| * \varphi\rangle.$$

Now we let ε go to 0, by hypothesis μ_{N^ε} converges to μ in $(\mathcal{C}^0(\Omega))^*$. Hence

$$\langle u_{N^\varepsilon}, \varphi\rangle \to \langle \mu, \ln|x| * \varphi\rangle.$$

This proves that u_{N^ε} converges to some u in the sense of distributions.

In the rest of the proof we drop the subscript ε and consider the limit $N \to +\infty$ (if N_ε stays bounded the proof is immediate). We follow closely the proof of Proposition 13.2 in [11]. We choose a bounded open set Ω' such that $\Omega \subset\subset \Omega'$. We can define μ_N, μ, u_N and u in Ω' (using formulas (32), (31) for u_N and μ_N valid in $\mathbb{R}^2$ and passing to the limit in Ω'). In Ω' we set

$$v_N = u_N - u, \qquad \alpha_N = \mu_N - \mu. \tag{33}$$

We then have

$$\Delta v_N = \alpha_N \ \text{ in } \Omega'. \tag{34}$$

It holds that $\lim\limits_{N\to+\infty} \|\alpha_N\|_{\mathcal{C}^0(\Omega')^*} = 0$. But since we have $W^{1,q}(\Omega') \hookrightarrow \mathcal{C}^0(\Omega')$ for $q > 2$ we also have $\mathcal{C}^0(\Omega')^* \hookrightarrow W^{-1,p}(\Omega')$ for $p < 2$. Thus we obtain

$$\lim_{N\to+\infty} \|\alpha_N\|_{W^{-1,p}(\Omega')} = 0 \text{ for } p < 2.$$

Now we let

$$\delta_N = \left(\frac{\|\alpha_N\|_{W^{-1,p}(\Omega')}}{\|\alpha_N\|_{\mathcal{C}^0(\Omega')^*} + 1}\right)^{1/2}, \quad F_N = \{x \in \Omega; |v_N| \geq \delta_N\}. \tag{35}$$

We have the following bound on the p-capacity of F_N (*cf.* [6] p.158)

$$\operatorname{cap}_p(F_N) \leq C \frac{\|v_n\|^p_{W^{1,p}(\Omega)}}{\delta_N^p}. \tag{36}$$

We note note that by elliptic regularity theory $\|v_N\|_{W^{1,p}(\Omega)} \leq C\|\alpha_N\|_{W^{-1,p}(\Omega')}$ because of (34) and because $\Omega \subset\subset \Omega'$. Thus from (35) and (36) we find that

$$\operatorname{cap}_p(F_N) \leq C\|\alpha_N\|^{p/2}_{W^{-1,p}(\Omega')}(\|\alpha_N\|_{\mathcal{C}^0(\Omega')^*} + 1)^{p/2},$$

and therefore tends to 0 as N goes to infinity. This implies in turn that

$$\lim_{N\to+\infty} \operatorname{cap}_1(F_N) = 0.$$

Now we use a cut-off function $\varphi \in \mathcal{C}^\infty(\overline{\Omega'})$ such that $|\varphi(x)| \le 1$ for all $x \in \Omega'$, $\varphi \equiv 1$ in Ω and $\varphi = 0$ on $\partial\Omega'$. We also set

$$\tilde{F_N} = \{x \in \Omega'; |\varphi v_N| \ge \delta_N\}.$$

We have that $F_N \subset \tilde{F_N}$ and $\tilde{F_N} \cap \Omega = F_N$ since $\varphi \equiv 1$ in Ω. We use the following truncated function:

$$\overline{\varphi v_N} = \begin{cases} \varphi v_N & \text{if} \quad |\varphi v_N| \le \delta_N, \\ \delta_N & \text{if} \quad |\varphi v_N| > \delta_N. \end{cases} \tag{37}$$

From a property of Sobolev functions (see *e.g.* Lemma 7.7 in [7]), we have $\nabla(\overline{\varphi v_N}) = 0$ almost everywhere in $\tilde{F_N}$. We thus obtain:

$$\begin{aligned} \int_{\Omega\setminus F_N} |\nabla v_N|^2 &\le \int_{\Omega'\setminus\tilde{F_N}} |\nabla(\varphi v_N)|^2 \\ &\le \int_{\Omega'} \nabla(\varphi v_N)\cdot\nabla(\overline{\varphi v_N}) \\ &\le \int_{\Omega'} -\Delta(\varphi v_N)\overline{\varphi v_N}. \end{aligned}$$

The last inequality being true since $\varphi = 0$ on $\partial\Omega'$. Using the Leibniz formula we obtain that

$$\Delta(\varphi v_N) = \Delta\varphi v_N + 2\nabla\varphi\cdot\nabla v_N + \varphi\Delta v_N.$$

Hence

$$\int_{\Omega\setminus F_N} |\nabla v_N|^2 \le \int_{\Omega'} |\Delta\varphi v_N(\overline{\varphi v_N})| + \int_{\Omega'} 2|\nabla\varphi||\nabla v_N||\overline{\varphi v_N}| + \int_{\Omega'} |\overline{\varphi v_N}| d\alpha_N$$

where we used the fact that $\Delta v_N = \alpha_N$ in Ω'. Now we use Hölder inequality to obtain that

$$\begin{aligned} \int_{\Omega\setminus F_N} |\nabla v_N|^2 &\le C\delta_N \left(\int_{\Omega'} |v_N|^p\right)^{1/p} + C\delta_N \left(\int_{\Omega'} |\nabla v_N|^p\right)^{1/p} + \delta_N \|\alpha_N\|_{\mathcal{C}^0(\Omega)^*} \\ &\le C\delta_N \left(\|v_N\|_{W^{1,p}(\Omega')} + \|\alpha_N\|_{\mathcal{C}^0(\Omega')^*}\right). \end{aligned}$$

Thus

$$\lim_{N\to+\infty} \|\nabla v_N\|_{L^2(\Omega\setminus F_N)} = 0. \tag{38}$$

We can also see, from the definition of F_N and because Ω is bounded that

$$\lim_{N\to+\infty} \|v_N\|_{L^2(\Omega\setminus F_N)} = 0. \tag{39}$$

We conclude as in [11]. Since $\lim_{n\to+\infty} \operatorname{cap}_1(F_N) = 0$, there is a subsequence, still denoted by $\{n\}$, such that $\sum_n \operatorname{cap}_1(F_N) < +\infty$. We define

$$E_\delta = \bigcup_{N>\frac{1}{\delta}} F_N.$$

Then $\mathrm{cap}_1(E_\delta)$ tends to zero as δ goes to zero since it is bounded above by the tail of a convergent series. Moreover, for any $\delta > 0$ we have $F_N \subset E_\delta$ when N is large enough and therefore (38) and (39) imply that

$$\lim_{N\to+\infty} \|v_N\|_{L^2(\Omega\setminus E_\delta)} = \lim_{N\to+\infty} \|\nabla v_N\|_{L^2(\Omega\setminus E_\delta)} = 0.$$

□

This proposition proves point 1) and 2) of Theorem 2.2. The next proposition shows that if we add the hypothesis that μ is in $H^{-1}(\Omega)$, then u weakly stationary harmonic implies u stationary harmonic.

Proposition 2.5 (Proposition 13.1 in [11]). *Assume that X is divergence-free in finite part in Ω and that X is in $L^1(\Omega \setminus E)$. Then for every $\zeta \in C_c^\infty(\Omega)$,*

$$\int_{\Omega\setminus F} X \cdot \nabla\zeta = 0,$$

where $F = \zeta^-1(\zeta(E))$. In particular if X is in $L^1(\Omega)$, then $F = \emptyset$ in the above and therefore $\operatorname{div} X = 0$ *in $\mathcal{D}'(\Omega)$.*

If μ is in $H^{-1}(\Omega)$ we have seen in the introduction that u is in $H^1(\Omega)$ and T_u is in $L^1(\Omega)$. Thanks to the previous proposition u weakly stationary harmonic implies u stationary harmonic.

3. First case: local behavior near a point z_0 such that $\omega_{h_\mu}(z_0) = (\partial_x h_\mu - i\partial_y h_\mu)^2(z_0) \neq 0$

Let us recall that we consider a couple (μ, h_μ) which satisfies

$$h_\mu \in H^1(\Omega) \tag{40}$$

$$\Delta h_\mu = \mu, \text{ in } \Omega \tag{41}$$

where μ is a Radon measure and

$$\omega_{h_\mu} = (\partial_x h_\mu)^2 - (\partial_y h_\mu)^2 - 2i\partial_x h_\mu \partial_y h_\mu \text{ is holomorphic in } \Omega \tag{42}$$

In this section we drop the subscript μ when there is no possible confusion. We denote by $B_r = B(z_0, r) = \{z \in \mathbb{C}; |z - z_0| < R\}$ the ball of center z_0 and of radius r. The starting point of the proof of Theorem 1.1 is the following:

Lemma 3.1. *Let h which satisfies* (40), (41), (42)*. Let $z_0 \in \Omega$ such that $\omega_h(z_0) \neq 0$. Then there exist $R > 0$, a function $\theta : B_R \to \{\pm 1\}$ and a harmonic function $H : B_R \to \mathbb{R}$ such that*

$$\partial_x h(z) - i\partial_y h(z) = \theta(z)\left[\partial_x H(z) - i\partial_y H(z)\right], \quad \forall\ z \in B_R. \tag{43}$$

Proof. It holds that

$$\omega_h = (\partial_x h)^2 - (\partial_y h)^2 - 2i\partial_x h\partial_y h = 4(\partial_z h)^2 = (\partial_x h - i\partial_y h)^2.$$

Thus $(\partial_x h - i\partial_y h)^2$ is a holomorphic function in Ω. If z_0 is such that $\omega_h(z_0) \neq 0$ then $f := (\partial_x h - i\partial_y h)^2$ satisfies that f is holomorphic in Ω and $\mathrm{f}(z_0) \neq 0$. This implies that in a neighborhood U of z_0 where $f(z)$ does not vanish there exists a function $g : U \to \mathbb{C}$ such that $g^2 = f$ in U. We can hence deduce that there exists $\theta : U \to \{\pm 1\}$ such that

$$\partial_x h - i\partial_y h = \theta(z)g(z) \text{ in } U.$$

From now on we take $U = B(z_0, R) =: B_R$ for R sufficiently small. We then set $H(z) := \mathrm{Re} \int_{z_0}^{z} g(s)ds$. This is well defined since B_R is simply connected. The function H satisfies the following properties:

1) H vanishes at z_0.
2) H is harmonic in B_R because it is the real part of an holomorphic function.
3) $2\partial_z H(z) = g(z)$ or equivalently $\partial_x H - i\partial_y H = g$

Thus

$$\partial_x h - i\partial_y h = \theta(\partial_x H - i\partial_y H), \text{ in } B_R. \tag{44}$$

Besides we have that $\nabla H(z_0) \neq 0$ since $|\nabla H(z_0)|^2 = |\omega_h(z_0)|^2 \neq 0$. □

We set:

$$B_R^+ := \{z \in B_R; \theta(z) = +1\} \quad B_R^- := \{z \in B_R; \theta(z) = -1\}. \tag{45}$$

Idea of the proof of Theorem 1.1 : The strategy of the proof is the following: we first show that the function θ is in $BV(B_R)$. Hence B_R^+ and B_R^- are sets of finite perimeter in B_R. It turns out that the support of $\mu_{\lfloor B_R}$ is equal to the essential boundary of B_R^+ minus the (topological) boundary ∂B_R. Then we use a theorem of structure of sets of finite perimeter in $\mathbb{R}^2$ due to Ambrosio-Caselles-Morel-Masnou in [1] to decompose the essential boundary of B_R^+ as a disjoint union of Jordan curves. Because of the relation (43) we are able to show that these Jordan curves are unions of some part of the boundary ∂B_R and of level curves of the harmonic function H. Since μ is a Radon measure we prove that there can not be an infinite number of level curves of H in the support of μ near z_0 (otherwise $\mu(B_R) = +\infty$). Then we can take a smaller open set V containing z_0 such that the support of $\mu_{\lfloor V}$ is the set of zeros of H. In V we can use the fact that $\nabla(h - \theta H) = 0$ or use the maximum principle to obtain that $h = +|H|$ or $h = -|H|$.

Lemma 3.2. *Let h which satisfies* (40), (41), (42). *Let $R > 0$ be small enough, $\theta : B_R \to \{\pm 1\}$ and $H : B_R \to \mathbb{R}$ such that* (43) *holds. Then θ is in $BV(B_R)$.*

Proof. We set $g = \partial_x H - i\partial_y H$. Since H is harmonic it holds that g is holomorphic. Since z_0 is not a zero of the function $f = (\partial_x h - i\partial_y h)^2$ we have that g does not vanish in B_R. Then we can write

$$\theta(z) = \frac{\partial_x h(z) - i\partial_y h(z)}{g(z)}.$$

We obtain that θ is in $L^1(B_R)$ since h is in $H^1(\Omega)$ and g is in $\mathcal{C}^\infty(\overline{B_R})$.
Furthermore we can differentiate θ in the sense of distributions using the Leibniz rule since $g \in \mathcal{C}^\infty(B_R)$. We obtain

$$\partial_x \theta = \frac{(\partial^2_{xx} h - i\partial^2_{yx} h)g - \partial_x g(\partial_x h - i\partial_y h)}{g^2}, \quad \partial_y \theta = \frac{(\partial^2_{xy} h - i\partial^2_{yy} h)g - \partial_y g(\partial_x h - i\partial_y h)}{g^2}.$$

Summing these two equalities it comes

$$\partial_x \theta + i\partial_y \theta = \frac{\Delta h}{g} - \frac{(\partial_x g + i\partial_y g)(\partial_x h - i\partial_y h)}{g^2}.$$

But since g is holomorphic in B_R it holds that $\partial_{\bar{z}} g = \frac{1}{2}[\partial_x g + i\partial_y g] = 0$. Hence $\partial_x \theta + i\partial_y \theta = \frac{\Delta h}{g}$. Now $\Delta h = \mu$ is a Radon measure and we can write $\partial_x \theta = \mathrm{Re}(\frac{1}{g})\Delta h$, $\partial_y \theta = \mathrm{Im}(\frac{1}{g})\Delta h$. Let us denote by $\langle ., . \rangle$ the duality bracket for distributions. For all $\varphi \in \mathcal{C}_c^1(B_R, \mathbb{R}^2)$ with $|\varphi| \leq 1$, we have

$$\int_{B_R} \theta \operatorname{div} \varphi = -\langle \partial_x \theta, \varphi_1 \rangle - \langle \partial_y \theta, \varphi_2 \rangle = -\int_{B_R} \operatorname{Re}(\frac{1}{g}) \varphi_1 d\mu - \int_{B_R} \operatorname{Im}(\frac{1}{g}) \varphi_2 d\mu.$$

Hence we obtain

$$|\int_{B_R} \theta \operatorname{div} \varphi| \leq \|\frac{1}{g}\|_{L^\infty} \mu(B_R) < +\infty$$

which means that θ is in $BV(B_R)$ by definition. □

Recall that a set $E \subset \Omega$ is a set of finite perimeter in Ω if its characteristic function χ_E is in $BV(\Omega)$. We have

$$\chi_{B_R^+} = \frac{1}{2}(1+\theta), \quad \chi_{B_R^-} = \frac{1}{2}(1-\theta).$$

Hence B_R^+ and B_R^- are sets of finite perimeter in B_R. We need several definitions and results from the theory of sets of finite perimeter we recall these notions now and we refer the reader to the books [6], or [2] for the proof of these results.

Theorem 3.1 ([6] p.167)**.** *Let E be a set of locally finite perimeter in Ω, then there exists a Radon measure on Ω denoted by $\|\partial E\|$ and a $\|\partial E\|$-measurable function $\nu_E : \Omega \to \mathbb{R}$ such that*

1) $|\nu_E(x)| = 1$ $\|\partial E\|$*- a.e. , and*
2) $\int_E \operatorname{div} \varphi dx = \int_\Omega \varphi \cdot \nu_E \, d\|\partial E\|$ *for all* $\varphi \in \mathcal{C}_c^1(\Omega, \mathbb{R}^n)$.

We present two notions of "boundary" of sets of finite perimeter:

Definition 3.1. *Let E be a set of locally finite perimeter in $\mathbb{R}^n$ and $x \in \mathbb{R}^n$. We say that $x \in \partial^\star E$, the reduced boundary of E, if*

i) $\|\partial E\|(B(x,r)) > 0$ *for all* $r > 0$,
ii) $\lim_{r \to 0} \frac{1}{|B(x,r)|} \int_{B(x,r)} \nu_E d\|\partial E\| = \nu_E(x)$, *and*
iii) $|\nu_E(x)| = 1$.

Definition 3.2. *Let E be a Lebesgue measurable set in $\mathbb{R}^n$ and $x \in \mathbb{R}^n$. We say $x \in \partial_\star E$, the measure theoretic boundary or essential boundary of E if*

$$\limsup_{r \to 0} \frac{|B(x,r) \cap E|}{r^n} > 0 \quad \textit{and} \quad \limsup_{r \to 0} \frac{|B(x,r) \setminus E|}{r^n} > 0.$$

(Here $|A|$ denotes the n-Lebesgue measure of a set in $\mathbb{R}^n$).

The structure of the reduced boundary of a set of locally finite perimeter in $\mathbb{R}^n$ is described by the following theorem:

Theorem 3.2 ([6] p.205)**.** *Assume E has locally finite perimeter in $\mathbb{R}^n$.*

i) *Then*

$$\partial^\star E = \bigcup_{k=1}^\infty K_k \cup N,$$

where

$$\|\partial E\|(N) = 0$$

and K_k is a compact subset of a $\mathcal{C}^1$-hypersurface S_k ($k = 1, 2, ...$).

ii) *Furthermore, $\nu_E | S_k$ is normal to S_k ($k = 1, ...$) and*
iii) $\|\partial E\| = \mathcal{H}^{n-1}_{\lfloor \partial^\star E}$.

We have a relation between the reduced and the essential boundary.

Proposition 3.1. i) $\partial^\star E \subset \partial_\star E$.

ii) $\mathcal{H}^{n-1}(\partial_\star E \setminus \partial^\star E) = 0$.

We will also use the following theorem

Theorem 3.3 (Gauss-Green formula [6] p.209). *Let $E \subset \mathbb{R}^n$ have locally finite perimeter.*

i) *Then $\mathcal{H}^{n-1}(\partial_\star E \cap K) < +\infty$ for each compact set $K \subset \mathbb{R}^n$.*

ii) *Furthermore, for $\mathcal{H}^{n-1}$ a.e. $x \in \partial_\star E$, there is a unique measure theoretic unit outer normal $\nu_E(x)$ such that*

$$\int_E \operatorname{div}(\varphi)dx = \int_{\partial_\star E} \varphi \cdot \nu_E d\mathcal{H}^{n-1} \tag{46}$$

for all $\varphi \in \mathcal{C}^1_c(\mathbb{R}^n, \mathbb{R}^n)$.

Since B_R^+ is a set of finite perimeter in B_R, we denote by $\nu_{B_R^+}$ its measure theoretic (or generalized) outer normal.

Lemma 3.3. *Let h as in Lemma 3.1. Let θ, H given by Lemma 3.1. Let $B_R^+ = \{z \in B_R; \theta(z) = +1\}$, thanks to Lemma 3.2, B_R^+ is a set of finite perimeter in B_R and we have: the generalized normal $\nu_{B_R^+}$ is collinear to ∇h and ∇H, $\mathcal{H}^1_{\lfloor \partial_\star B_R^+ \setminus \partial B_R}$ almost everywhere in B_R.*

Proof. Let us recall that, because of (43) we have

$$\partial_x h - i\partial_y h = \theta(\partial_x H - i\partial_y H). \tag{47}$$

In the sense of distributions we have $\partial_x\partial_y h = \partial_y\partial_x h$. Thus we obtain $\partial_y(\theta\partial_x H) = \partial_x(\theta\partial_y H)$ and

$$\partial_y\theta\partial_x H + \theta\partial_y\partial_x H = \partial_x\theta\partial_y H + \theta\partial_x\partial_y H. \tag{48}$$

Now since H is harmonic and hence $\mathcal{C}^\infty(B_R)$ it holds that $\partial^2_{xy} H = \partial^2_{yx} H$. Hence

$$\partial_y\theta\partial_x H = \partial_x\theta\partial_y H.$$

Thus for all $\varphi \in \mathcal{C}^\infty_c(B_R, \mathbb{R})$ we have

$$\begin{aligned}
\langle \partial_y\theta\partial_x H, \varphi\rangle &= \langle \partial_x\theta\partial_y H, \varphi\rangle \\
\langle \partial_y\theta, \partial_x H\varphi\rangle &= \langle \partial_x\theta, \partial_y H\varphi\rangle \\
\langle \partial_x\theta, -\partial_y H\varphi\rangle + \langle \partial_y\theta, \partial_x H\varphi\rangle &= 0 \\
\int_{B_R} \theta \operatorname{div}\psi &= 0 \\
\int_{B_R^+} \operatorname{div}\psi - \int_{B_R^-} \operatorname{div}\psi &= 0.
\end{aligned}$$

where in the last equalities we set $\psi := (-\partial_y H\varphi, \partial_x H\varphi)$. We then use Theorem 3.3 to obtain

$$\int_{\partial_\star B_R^+} \psi \cdot \nu_{B_R^+} d\mathcal{H}^1 - \int_{\partial_\star B_R^-} \psi \cdot \nu_{B_R^-} d\mathcal{H}^1 = 0.$$

But $\partial_\star B_R^+ = \partial_\star B_R^-$ and $\nu_{B_R^+} = -\nu_{B_R^-}$ because $B_R^+ = B_R \setminus B_R^-$. Hence we obtain

$$2\int_{\partial_\star B_R^+} \psi \cdot \nu_{B_R^+} d\mathcal{H}^1 = 0.$$

Using the fact that φ has compact support in B_R and the definition of ψ we find that

$$\int_{\partial_\star B_R^+\setminus\partial B_R}(-\partial_y H\nu^1_{B_R^+}+\partial_x H\nu^2_{B_R^+})\varphi d\mathcal{H}^1=0 \tag{49}$$

for all $\varphi\in\mathcal{C}^1_c(B_R,\mathbb{R}^2)$, where we denoted $\nu_{B_R^+}=(\nu^1_{B_R^+},\nu^2_{B_R^+})$. We conclude from (49) that

$$-\partial_y H\nu^1_{B_R^+}+\partial_x H\nu^2_{B_R^+}=0,\ \mathcal{H}^1-\text{a.e. on }\partial_\star B_R^+\setminus\partial B_R.$$

The last equality means that $\nu_{B_R^+}$ is orthogonal to $(-\partial_y H,\partial_x H)$ $\mathcal{H}^1$-a.e on $\partial_\star B_R^+\setminus\partial B_R$ and hence parallel to $(\partial_x H,\partial_y H)$. We also obtain that $\nu_{B_R^+}$ is collinear to ∇h because $\nabla h=\theta\nabla H$ in B_R. □

We can now describe the support of the measure $\mu_{\lfloor B_R}$ in terms of the boundary of B_R^+.

Lemma 3.4. *Let h satisfy the hypothesis* (40), (41), (42). *Let θ, H, B_R, B_R^+ as in Lemma 3.1. Then the support of $\mu_{\lfloor B_R}$ is $\partial_\star B_R^+\setminus\partial B_R$ and we have*

$$\mu_{\lfloor B_R}=-2\nabla H\cdot\nu_{B_R^+}\mathcal{H}^1_{\lfloor\partial_\star B_R^+\setminus\partial B_R}.$$

Proof. It holds that

$$\begin{aligned}\langle\Delta h,\varphi\rangle &= -\int_{B_R}\nabla h\cdot\nabla\varphi,\quad\forall\varphi\in\mathcal{C}^\infty_c(B_R)\ \ (h\in H^1(\Omega))\\ &= -\int_{B_R^+}\nabla H\cdot\nabla\varphi+\int_{B_R^-}\nabla H\cdot\nabla\varphi\ \ (\nabla h=\pm1\nabla H\text{ in }B_R^\pm)\end{aligned}$$

Now we use the fact that H is harmonic in B_R ($\Delta H=0$ in B_R) and the Gauss-Green formula 3.3 to obtain

$$\begin{aligned}\langle\Delta h,\varphi\rangle &= -\int_{\partial_\star B_R^+\setminus\partial B_R}\varphi\nabla H\cdot\nu_{B_R^+}d\mathcal{H}^1+\int_{\partial_\star B_R^-\setminus\partial B_R}\varphi\nabla H\cdot\nu_{B_R^-}d\mathcal{H}^1\\ &= -2\int_{\partial_\star B_R^+\setminus\partial B_R}\varphi\nabla H\cdot\nu_{B_R^+}d\mathcal{H}^1\end{aligned}$$

since $\partial_* B_R^+=\partial_* B_R^-$ and $\nu_{B_R^+}=-\nu_{B_R^-}$. Now because of the previous Lemma 3.3 we have that $|\nabla H\cdot\nu_{B_R^+}|=|\nabla H|\neq 0$ in B_R (recall that $|\nabla H|=|\nabla h|$ in B_R). Hence we can deduce that the support of $\mu_{\lfloor B_R}$ is $\partial_* B_R^+\setminus\partial B_R$ and the lemma is proved. □

We study in more details $\partial_\star B_R^+\setminus\partial B_R$. In particular since ∇h and $\nu_{B_R^+}$ are parallel on $\partial_\star B_R^+\setminus\partial B_R$ we expect H to be constant on the connected components of this set. In order to prove this fact we need more definitions and more results from geometric measure theory, these can be found in the article [1].

Definition 3.3. *A curve $\Gamma\subset\mathbb{R}^2$ is a Jordan curve if $\Gamma=\gamma([a,b])$ for some $a,b\in\mathbb{R}$ with $a<b$, and some continuous map γ, one-to-one on $[a,b)$ and such that $\gamma(a)=\gamma(b)$.*

Definition 3.4. *A curve $\Gamma\subset\mathbb{R}^2$ is rectifiable if $\mathcal{H}^1(\Gamma)<\infty$.*

Lemma 3.5 (Lemma 3 in [1])**.** *Let $C\subset\mathbb{R}^n$ be a compact connected set with $\mathcal{H}^1(C)<\infty$. Then for any pair of distinct points $x,y\in C$ there exists a Lipschitz one-to-one map $\gamma:[0,1]\to C$ such that $\gamma(0)=x$ and $\gamma(1)=y$.*

A consequence of this lemma is that any rectifiable Jordan curve admits a Lipschitz re-parametrization.

In order to state the next theorem, following [1], we introduce a *formal* Jordan curve J_∞ whose interior is $\mathbb{R}^n$ and a *formal* Jordan curve J_0 whose interior is empty. We denote by $\mathcal{S}$ the set of Jordan curves and formal Jordan curves. We then have the following description of the essential boundary of sets of finite perimeter in $\mathbb{R}^2$.

Theorem 3.4 (Corollary 1 in [1]). *Let E be a subset of $\mathbb{R}^2$ of finite perimeter. Then there is a unique decomposition of $\partial_\star E$ into rectifiable Jordan curves $\{C_i^+, C_k^- : i,k \in \mathbb{N}\} \subset \mathcal{S}$, such that*

- i) *Given $\mathrm{int}(C_i^+), \mathrm{int}(C_k^+), i \neq k$, they are either disjoint or one is contained in the other; given $\mathrm{int}(C_i^-), \mathrm{int}(C_k^-), i \neq k$, they are either disjoint or one is contained in the other. Each $\mathrm{int}(C_i^-)$ is contained in one of the $\mathrm{int}(C_k^+)$.*
- ii) *$P(E) = \sum_i \mathcal{H}^1(C_i^+) + \sum_k \mathcal{H}^1(C_k^-)$.*
- iii) *If $\mathrm{int}(C_i^+) \subset \mathrm{int}(C_j^+)$, $i \neq j$, then there is some rectifiable Jordan curve C_k^- such that $\mathrm{int}(C_i^+) \subset \mathrm{int}(C_k^-) \subset \mathrm{int}(C_j^+)$. Similarly if $\mathrm{int}(C_i^-) \subset \mathrm{int}(C_j^-)$, $i \neq j$, then there is some rectifiable Jordan curve C_k^+ such that $\mathrm{int}(C_i^-) \subset \mathrm{int}(C_k^+) \subset \mathrm{int}(C_j^-)$.*
- iv) *Setting $L_j = \{i;\ \mathrm{int}(C_i^- \subseteq \mathrm{int}(C_j^+)\}$, the sets $Y_j = \mathrm{int}(C_j^+) \setminus \cup_{i\in L_j} \mathrm{int}(C_i^-)$ are pairwise disjoint, indecomposable and $E = \cup_j Y_j$.*

We are now able to prove:

Lemma 3.6. *Let θ be such that* (43) *holds, $\theta \in BV(B_R)$. Let B_R^+ as before. There exist (possibly infinitely many) disjoint rectifiable Jordan curves γ_i such that*

$$\partial_\star B_R^+ = \bigcup_{i=1}^{+\infty} \gamma_i.$$

Proof. We must check that B_R^+ is a set of finite perimeter in $\mathbb{R}^2$ (not just in B_R) in order to apply Theorem 3.4. To this end we set

$$\tilde{\theta} := \begin{cases} \theta \text{ if } x \in B_R, \\ -1 \text{ if } x \in \mathbb{R}^2 \setminus B_R. \end{cases}$$

We also set $\chi_{B_R^+} = \frac{1}{2}(1+\tilde{\theta})$, this is the characteristic function of B_R^+ in $\mathbb{R}^2$. We must prove that $\chi_{B_R^+} \in BV(\mathbb{R}^2)$. First we note that $\chi_{B_R^+} \in L^1(\mathbb{R}^2)$ because it is bounded in B_R and it is null in $\mathbb{R}^2 \setminus B_R$. Second for all $\varphi \in \mathcal{C}_c^\infty(\mathbb{R}^2, \mathbb{R}^2)$ we have

$$\int_{\mathbb{R}^2} \chi_{B_R^+} \mathrm{div}(\varphi) = \frac{1}{2}\int_{\mathbb{R}^2} \tilde{\theta}\, \mathrm{div}(\varphi)$$

since φ has compact support in $\mathbb{R}^2$. Thus

$$\begin{aligned}\int_{\mathbb{R}^2} \chi_{B_R^+} \mathrm{div}(\varphi) &= \frac{1}{2}\left[\int_{B_R} \theta\, \mathrm{div}(\varphi) - \int_{\mathbb{R}^2\setminus B_R} \mathrm{div}(\varphi)\right] \\ &= \frac{1}{2}\int_{B_R^+} \mathrm{div}(\varphi) - \frac{1}{2}\int_{B_R^-} \mathrm{div}(\varphi) - \frac{1}{2}\int_{\mathbb{R}^2\setminus B_R} \mathrm{div}(\varphi).\end{aligned}$$

Now we claim that B_R^+, B_R^- and $\mathbb{R}^2 \setminus B_R$ have locally finite perimeter in $\mathbb{R}^2$. This is obvious for $\mathbb{R}^2 \setminus B_R$ because B_R is a smooth open set with finite perimeter in $\mathbb{R}^2$. For B_R^+, B_R^- thanks to a deep criterion (*cf.* Theorem 1 p.222 of [6]) we must only check that for all K compact subset of $\mathbb{R}^2$

$$\mathcal{H}^1(K \cap \partial_\star B_R^+) < +\infty.$$

But $\mathcal{H}^1(K\cap\partial_\star B_R^+)\leq\mathcal{H}^1(\overline{B_R}\cap\partial_\star B_R^+)<+\infty$ because B_R^+ has finite perimeter in B_R by definition, and the same is true for B_R^-. We can thus apply the Gauss-Green formula 3.3 to obtain

$$\int_{\mathbb{R}^2}\tilde{\theta}\,\mathrm{div}(\varphi)=\int_{\partial_\star B_R^+}\varphi\cdot\nu_{B_R^+}d\mathcal{H}^1-\int_{\partial_\star B_R^-}\varphi\cdot\nu_{B_R^-}d\mathcal{H}^1-\int_{\partial B_R}\varphi\cdot\nu_{B_R}d\mathcal{H}^1.$$

Hence for all $\varphi\in\mathcal{C}_c^\infty(\mathbb{R}^2,\mathbb{R}^2)$ we have

$$|\int_{\mathbb{R}^2}\tilde{\theta}\,\mathrm{div}(\varphi)|\leq 2\mathcal{H}^1(\partial_\star B_R^+)+\mathcal{H}^1(\partial B_R)<+\infty.$$

This proves that $\chi_{B_R^+}$ is in $BV(\mathbb{R}^2)$. We can thus apply the Theorem 3.4 to obtain the lemma. □

In order to pursue the proof of the main result we need the following version of the coarea formula:

Theorem 3.5 (Theorem 2.93 in [2] p.101)**.** *Let $f:\mathbb{R}^2\to\mathbb{R}$ be a Lipschitz function and let E be a countably $\mathcal{H}^1$-rectifiable subset of $\mathbb{R}^2$. Then the function $t\mapsto\mathcal{H}^0(E\cap f^{-1}(t))$ is Lebesgue measurable in $\mathbb{R}$, $E\cap f^{-1}(t)$ is countably $\mathcal{H}^0$-rectifiable for dt-a.e. $t\in\mathbb{R}$ and*

$$\int_E C_k d^E f_x d\mathcal{H}^1(x)=\int_{\mathbb{R}}\mathcal{H}^0(E\cap f^{-1}(t))dt. \tag{50}$$

where d^Ef_x is the tangential differential of f at $x\in E$, $C_kd^Ef_x$ is the k-dimensional coarea factor, $\mathcal{H}^0$ is the 0-dimensional Hausdorff measure (this is the counting measure) and for the definitions of these notions we refer to [2] *Chapter 2.*

We can apply the previous theorem with the function $f:\mathbb{R}^2\to\mathbb{R}$, $x\mapsto|x|$ (we have that $|d^Ef_x|\leq 1$ for this f and all E countably $\mathcal{H}^1$-rectifiable subset of $\mathbb{R}^2$). We then find that for all rectifiable Jordan curves γ we have, for $R>\rho>0$

$$\mathcal{H}^1(\gamma\cap(B_R\setminus B_{R-\rho}))\geq\int_{R-\rho}^R\mathcal{H}^0(\gamma_i\cap C_t)dt \tag{51}$$

where $C_t=\{z\in\mathbb{R}^2;|z|=t\}$. We then obtain:

Lemma 3.7. *Under the same assumptions as in Lemma 3.6. There exist $0<R'<R$ and (possibly infinitely many) connected rectifiable simple curves Γ_j such that*

$$\partial_\star B_{R'}^+\setminus\partial B_{R'}=\bigcup_{j=1}^{+\infty}\Gamma_j. \tag{52}$$

Proof. We use the formula (51), and the fact that $\mathcal{H}^0(\gamma_i\cap C_t)$ is finite for almost every $t\in[R-\rho,R]$. We choose R' such that $\mathcal{H}^0(\gamma_i\cap C_{R'})<+\infty$ and we have that for all $i\in\mathbb{N}$ there exists $k_i\in\mathbb{N}$ and k_i intervals of $\mathbb{R}$ such that

$$\gamma_i\cap B_{R'}=\gamma_i(I_1)\cup...\cup\gamma_i(I_{k_i})$$

with $I_j=]a_j,b_j[$ and $\gamma_i(a_j),\gamma_i(b_j)\in\partial B_{R'}$ for $j=1,...,k_i$. Hence $\gamma_i\cap B_{R'}$ is a finite union of connected rectifiable simple curves. We define $B_{R'}^+=B_R^+\cap B_{R'}$ and we find that

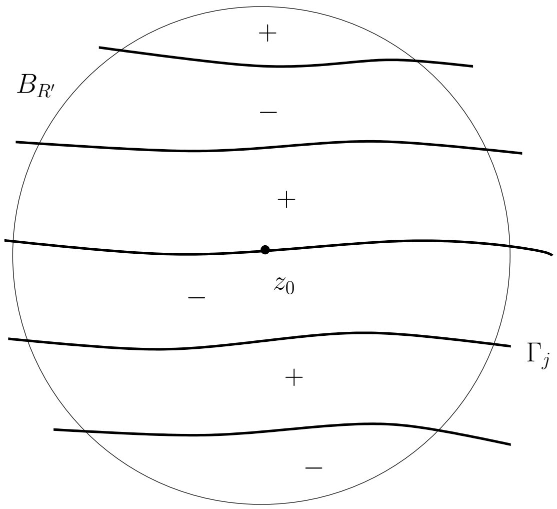

Figure 4. Illustration of Lemma 3.7

$$\begin{aligned}\operatorname{supp}\mu_{\lfloor B_{R'}} &= \partial_\star B^+_{R'} \setminus \partial B_{R'} = \operatorname{supp}\mu_{\lfloor B_R} \cap B_{R'}\\ &= \bigcup_{i=1}^{+\infty} \gamma_i \cap B_{R'} = \bigcup_{j=1}^{+\infty} \Gamma_j\end{aligned}$$

with Γ_j connected rectifiable simple curves. □

We are now in position to prove Theorem 1.1.

Proof of Theorem 1.1. Let h which satisfies (40), (41),(42). Let θ, H be defined by (43). Let $R' > 0$ be as in Lemma 3.7. From now on we denote by B the ball $B_{R'}$. We also denote by $B^+ = \{z \in B; \theta(z) = +1\}$. Let $\{\Gamma_j\}_{j\in\mathbb{N}}$ simple connected rectifiable given by Lemma 3.7. The next claim states that each connected component of $\partial_\star B^+ \setminus \partial B$ is a connected component of some level curve of the function H in B.

Claim 3.1. *For all $i \in \mathbb{N}$, there exists $c_i \in \mathbb{R}$ such that*

$$\Gamma_i = \{z \in \mathbb{R}^2; H(z) = c_i\} \cap B.$$

1) We first show that for all $i \in \mathbb{N}$ there exists $c_i \in \mathbb{R}$ such that $\Gamma_i \subset \{H = c_i\} \cap B$, where $\{H = c_i\}$ is a short for $\{z \in \mathbb{R}^2; H(z) = c_i\}$. Indeed let $x, y \in \Gamma_i$, $x \neq y$, thanks to Lemma 3.5 we can find a bijective lipschitz map $f : [0,1] \to \Gamma_i$ such that $f(0) = x$ and $f(1) = y$. We then have

$$H(y) - H(x) = \int_0^1 \frac{d}{dt}(H \circ f)(t)dt$$

because $H \circ f \in W^{1,1}([0,1],\mathbb{R})$, (that is $H \circ f$ is absolutely continuous). To prove the absolute continuity we use that $H \in \mathcal{C}^\infty(\overline{B})$ and $f \in W^{1,\infty}([0,1], B)$. Hence (we obtain that $H \circ f \in W^{1,\infty}([0,1]) \subset W^{1,1}([0,1])$ (see *e.g.* Proposition 9.5 p. 270 of [4]). Thus

$$H(y) - H(x) = \int_0^1 \nabla H(f(t) \cdot f'(t)dt$$

where $f'(t)$ denotes the derivative of f which exists for $\mathcal{L}^1$-almost every $t \in [0,1]$ (because Lipschitz functions are differentiable almost everywhere). But $f'(t)$ is tangent to Γ_i and $\nabla H(f(t))$ is orthogonal to $f'(t)$ for almost every $t \in [0,1]$. Indeed thanks to Lemma 3.3, we have that ∇H parallel to ν_{B^+} $\mathcal{H}^1$-a.e. Hence we obtain that

$\nabla H(f(t)) \cdot f'(t) = 0$ a.e. and $H(y) = H(x)$. This shows that $\Gamma_i \subset \{H = c_i\} \cap B$.

2) We show that $\Gamma_i = \{H = c_i\} \cap B$ using the following Lemma 3.8. We use the fact that since ∇H does not vanish in B the level curves $\{H = c_i\} \cap B$ are diffeomorphic to straight line (this is a consequence of the implicit function theorem or can be seen in Theorem 1.3) if R' is small enough. Hence they are connected. We then apply Lemma 3.8 to Γ_i and $\{H = c_i\} \cap B$. These two curves are rectifiable, connected and simple, and we have $\Gamma_i \subset \{H = c_i\} \cap B$ and $\Gamma_i \cap \partial B = \{H = c_i\} \cap \partial B$ by continuity of H.

Lemma 3.8. *Let B be a ball of radius R. Let γ and $\tilde{\gamma}$ be two connected rectifiable simple curves. We also denote by $\gamma, \tilde{\gamma} : [0,1] \to \mathbb{R}^2$ some Lipschitz parametrization of these curves. We suppose that γ, $\tilde{\gamma}$ are homeomorphism from $[0,1]$ onto their image. Assume that*

i) $\gamma(]0,1[) \subset B$ *and* $\gamma(0), \gamma(1) \in \partial B$,
ii) $\tilde{\gamma}(]0,1[) \subset B$ *and* $\tilde{\gamma}(0), \tilde{\gamma}(1) \in \partial B$,
iii) $\tilde{\gamma}([0,1]) \subset \gamma([0,1])$.

Then $\gamma = \tilde{\gamma}$.

We postpone the proof of this lemma at the end of the section. Now that we know the geometry of the curves Γ_i we can prove that there exists only a finite number of such curves in a sufficiently small ball.

Claim 3.2. *Let $\rho > 0$ small enough such that $\Gamma_i \cap B(z_0, \rho) = \{H = c_i\} \cap B(z_0, \rho)$ is diffeomorphic to an open segment for all $i \in \mathbb{N}$ such that $\Gamma_i \neq \emptyset$. Then there exists a finite number of curves Γ_i such that $\Gamma_i \cap B(z_0, \rho) \neq \emptyset$.*

With ρ as in the statement of the claim we let $B_\rho = B(z_0, \rho)$. Since $\theta \in BV(B_R)$ we also have $\theta \in BV(B_\rho)$.Thus using the same notations as before we have

$$\begin{aligned} +\infty &> \mathcal{H}^1(\partial_\star B_\rho^+ \setminus \partial B_\rho) \\ &= \mathcal{H}^1(\mathrm{supp}(\mu_{\lfloor B_\rho})) \\ &= \mathcal{H}^1(\bigcup_{i=1}^{+\infty} \Gamma_i \cap B_\rho) \\ &\geq \int_0^\rho \mathcal{H}^0(\bigcup_{i=1}^{+\infty} \Gamma_i \cap C_t) dt \end{aligned}$$

where in the last equality we used the coarea formula (Theorem 3.5), and we let $C_t = \{z \in \mathbb{C}; |z| = t\}$. The coarea formula also tells us that for almost every $t \in [0, \rho]$ we have $\mathcal{H}^0(\bigcup_{i=1}^{+\infty} \Gamma_i \cap C_t) < +\infty$. But if ρ is small enough then every level curves of the harmonic function H meet the boundary of the ball B_ρ. This is a consequence of the maximum principle. As a consequence we have that $\mathcal{H}^0(\bigcup_{i=1}^{+\infty} \Gamma_i \cap C_t)$ is exactly two times the number of curves Γ_i inside B_t. Then the number of curves Γ_i is finite inside B_ρ.

We can now conclude the proof of Theorem 1.1. The last claim proved that there exists a finite number of Γ_i near $Z_0 := \{z \in B; H(z) = 0\}$. Thus there exists $\eta > 0$ such that $\mathrm{dist}(Z_0, \Gamma_i) > \eta$ for all $i \in \mathbb{N}$ such that Γ_i is not included in Z_0. We then set $V := B(z_0, \frac{\eta}{2})$. Because of the definition of η we obtain that

$$\mathrm{supp}(\mu_{\lfloor V}) = \{z \in; H(z) = 0\}.$$

Note that Z_0 is a smooth connected rectifiable curve near z_0 (since $\nabla H(z_0) \neq 0$). We also set as usual $V^+ = \{z \in V; \theta(z) = +1\}$, $V^- = \{z \in V; \theta(z) = -1\}$. We have that

$$\nabla h = +\nabla H, \quad \text{on } V^+, \quad \nabla h = -\nabla H, \quad \text{on } V^-.$$

We thus deduce that $h = H$ on V^+ and $h = -H$ on V^- because $h = H = 0$ on $\partial_\star V^+ \setminus \partial V = Z_0$. We know that H does not vanish in V^+ and V^-, because H vanishes only on Z_0. Hence H has constant sign on V^+ and on V^- thanks to the maximum principle. These two signs are opposite, because if they were the same then the minimum (or maximum) of H would be 0 and would be inside the domain V, this contradicts the maximum principle. We can assume for example that H is non negative in V^+ and then $h = |H|$ in V.

□

Proof of Lemma 3.8. By contradiction, assume that there exists $p \in \gamma \setminus \tilde{\gamma}$. Let $t_0 \in]0,1[$ such that $\gamma(t_0) = p$. Then we have

$$]0,1[= \tilde{\gamma}^{-1}\big(\gamma(]0,t_0[) \cup \gamma(]t_0,1[)\big)$$

since $\tilde{\gamma}(]0,1[) \subset \gamma(]0,1[)$ and since $\gamma(t_0) \notin \tilde{\gamma}$. We then deduce that

$$]0,1[= \tilde{\gamma}^{-1}\left(\gamma(]0,t_0[)\right) \cup \tilde{\gamma}^{-1}\left(\gamma(]t_0,1[)\right).$$

But since $\tilde{\gamma}$ and γ are homeomorphism onto their image we have that $\tilde{\gamma}^{-1}(\gamma(]0,t_0[))$ and $\tilde{\gamma}^{-1}(\gamma(]t_0,1[))$ are two disjoint open sets. Thanks to the connectedness of $]0,1[$ we can deduce that

1) $\tilde{\gamma}^{-1}(\gamma(]0,t_0[)) =]0,1[$ and $\tilde{\gamma}^{-1}(\gamma(]t_0,1[)) = \emptyset$ or
2) $\tilde{\gamma}^{-1}(\gamma(]0,t_0[)) = \emptyset$ and $\tilde{\gamma}^{-1}(\gamma(]t_0,1[)) =]0,1[$.

These two cases are similar. Let us assume that we are in case 1). We can then obtain that

$$\gamma(]t_0,1[) \cap \tilde{\gamma}(]0,1[) = \emptyset.$$

This implies that $\gamma(]t_0,1[) = \emptyset$ or $\tilde{\gamma} \not\subseteq \gamma$. The first assertion is impossible because γ is assumed to be a homeomorphism from $[0,1]$ onto its image and the second possibility is in contradiction with the hypothesis iii). Thus it holds that $\tilde{\gamma} = \gamma$. □

4. SECOND CASE: LOCAL BEHAVIOR NEAR A ZERO OF EVEN ORDER OF $\omega_{h_\mu}(z) = (\partial_x h_\mu - i\partial_y h_\mu)^2(z)$

This section is devoted to the proof of Theorem 1.2. It is very similar to the proof of Theorem 1.1. Here $\omega_{h_\mu}(z_0) = 0$, but since we assume that z_0 is a zero of even order of ω_{h_μ} there is no difficulty to find a holomorphic function g such that $(\partial_x h_\mu - i\partial_y h_\mu)^2 = g(z)^2$. Then the proof of Theorem 1.2 is a rather direct adaptation of the proof of Theorem 1.1 except that here because the function g vanishes at z_0 we can only show that the function θ defined as in the previous section is in $BV_{loc}(B_R \setminus \{z_0\})$ for R sufficiently enough. This introduce a new technical difficulty. We drop the subscript μ in the rest of this section.

Lemma 4.1. *Let h which satisfies* (40), (41), (42). *Let $z_0 \in \Omega$ be a zero of even order of $\omega_h(z) = (\partial_x h - i\partial_y h)^2(z)$. Then there exist $R > 0$, a function $\theta : B_R \to \{\pm 1\}$ and a harmonic function $H : B_R \to \mathbb{R}$ such that*

$$\partial_x h(z) - i\partial_y h(z) = \theta(z)\left(\partial_x H(z) - i\partial_y H(z)\right), \quad \forall\, z \in B_R \tag{53}$$

Proof. Since z_0 is a zero of even order of ω_h, we can find a neighborhood U of z_0, $n \in \mathbb{N}$ and a holomorphic function $f_1 : U \to \mathbb{C}$ such that $f_1(z_0) \neq 0$ and

$$(\partial_x h - i\partial_y h)^2 = (z - z_0)^{2n} f_1(z). \tag{54}$$

Since $f_1(z_0) \neq 0$, we can choose a smaller neighborhood of z_0 still denoted by U such that in U there exists a holomorphic function denoted by φ_1 which satisfies $\varphi_1^2(z) = f_1(z)$, and furthermore we can choose $U = B(z_0, R)$ for R small enough. We then have

$$(\partial_x h - i\partial_y h)^2 = [(z - z_0)^n \varphi(z)]^2 =: g(z)^2. \tag{55}$$

We set $F(z) := \int_{z_0}^{z} g(s)ds$ and

$$H(z) := \mathrm{Re} F(z) = \mathrm{Re}\left(\int_{z_0}^{z} g(s)ds\right). \tag{56}$$

The function H is harmonic in B_R and satisfies

$$2\partial_z H = F'(z) = g(z) = (z - z_0)^n \varphi_1(z).$$

Hence, thanks to (54) we deduce that there exists $\theta : U \to \{\pm 1\}$ such that

$$\partial_x h - i\partial_y h = \theta(z)(\partial_x H - i\partial_y H) \tag{57}$$

□

As before we set

$$B_R^+ := \{z \in B_R; \theta(z) = +1\}, \quad B_R^- := \{z \in B_R; \theta(z) = -1\}.$$

We thus obtain that

$$\nabla h = +\nabla H, \text{ on } B_R^+, \quad \nabla h = -\nabla H, \text{ on } B_R^-.$$

Lemma 4.2. *Let h which satisfies* (40), (41), (42). *Let $R > 0$ be small enough and $\theta : B_R \to \{\pm 1\}$ such that* (57) *holds with H defined by* (56). *Then the function θ is in $BV_{loc}(B_R \setminus \{z_0\})$.*

Proof. In order to prove this result we can apply Lemma 3.2 of the previous section in any open subset $W \subset B_R$ such that $g = \partial_x H - i\partial_y H$ does not vanish in W. □

Thus B_R^+ and B_R^- are sets of locally finite perimeter in $B_R \setminus \{z_0\}$.

Lemma 4.3. *Let h as in Lemma 4.1. Let θ, H given by Lemma 4.1. Let $B_R^+ = \{z \in B_R; \theta(z) = +1\}$, thanks to Lemma 4.2 B_R^+ is a set of locally finite perimeter in $B_R \setminus (\{z_0\})$. Furthermore the generalized normal $\nu_{B_R^+}$ is collinear to ∇h and ∇H, $\mathcal{H}^1_{\lfloor \partial_\star B_R^+ \setminus \partial B_R}$ almost everywhere in B_R.*

The proof of this lemma is exactly the same as the one of Lemma 3.3. We can also copy the proof of Lemma 3.4 to obtain

Lemma 4.4. *Let h satisfy the hypothesis* (40), (41), (42). *Let θ, B_R, B_R^+ as in the previous lemma 3.3. Then the support of $\mu_{\lfloor B_R}$ is $\partial_\star B_R^+ \setminus \partial B_R$ and we have*

$$\mu_{\lfloor B_R} = -2\nabla H \cdot \nu_{B_R^+} \mathcal{H}^1_{\lfloor \partial_* B_R^+ \setminus \partial B_R}.$$

We would like to apply Theorem 3.4 to the set B_R^+ and continue the proof as in the previous section but we can not do that because B_R^+ have only *locally* finite perimeter in $B_R \setminus \{z_0\}$. In fact we will show that this is just a technical issue and that B_R^+ has indeed finite perimeter in B_R but it requires some work. In a first time we work in an annular domain. Let $0 < \rho < R$, we set

$$A_{R,\rho} = \{z \in \mathbb{C}; \rho < |z| < R\} \quad A_{R,\rho}^+ = \{z \in A_{R,\rho}; \theta(z) = +1\}.$$

We first apply Theorem 3.4 to the set $A_{R,\rho}^+$.

Lemma 4.5. *Let θ be such that* (53) *holds, $\theta \in BV_{loc}(B_R \setminus \{z_0\})$. Let $A_{R,\rho}^+$ as before. There exist (possibly infinitely many) disjoint rectifiable Jordan curves γ_i^ρ such that*

$$\partial_\star A_{R,\rho}^+ = \bigcup_{i=1}^{+\infty} \gamma_i^\rho.$$

Proof. We have that $\theta \in BV(A_{R,\rho})$. As in the proof of Lemma 3.6 one can show that $A_{R,\rho}^+$ has finite perimeter in $\mathbb{R}^2$. We can then apply Theorem 3.4 to deduce the result. □

Lemma 4.6. *Under the same assumptions as Lemma 4.5, there exist $0 < \rho < \rho' < R' < R$ and (possibly infinitely many) connected rectifiable simple curves Γ_j^ρ such that*

$$\partial_\star (A_{R',\rho'}^+) \setminus \partial(A_{R',\rho'}) = \bigcup_{j=1}^{\infty} \Gamma_j^{\rho'} \tag{58}$$

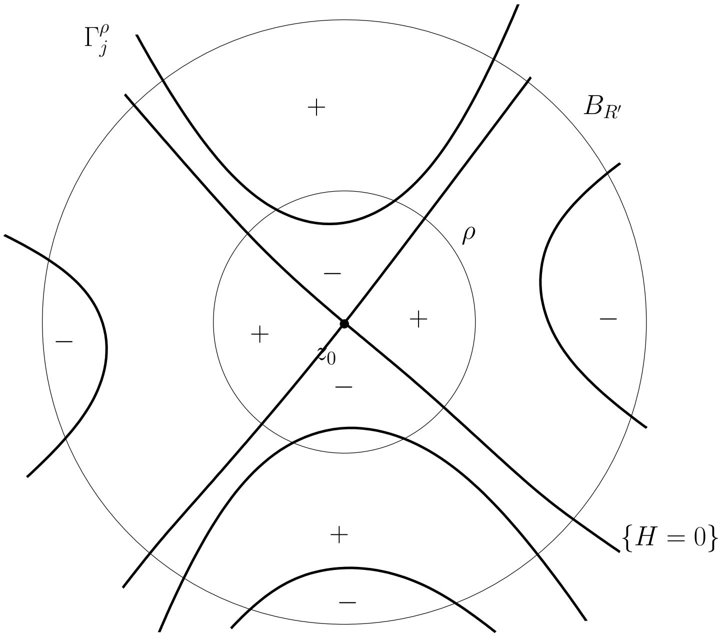

Figure 5. Illustration of Lemma 4.6

Proof. The proof is the same as in Lemma 3.7, it uses the coarea formula (see 3.5). □

Lemma 4.7. *Under the same assumptions as in Lemma 4.5, for all $j \in \mathbb{N}$, there exists $c_j^{\rho'} \in \mathbb{R}$ such that $\Gamma_i^{\rho'}$ is exactly one connected component of $\{z \in \mathbb{R}^2; H(z) = c_i^{\rho'}\} \cap A_{R',\rho'}$.*

Proof. Again in order to prove this lemma we can follow line by line the proof of claim 3.1. The only difference is that here $\{z \in \mathbb{R}^2; H(z) = c_i\} \cap A_{R',\rho'}$ is not necessarily connected if $c_i \neq 0$. □

Lemma 4.8. *Under the same assumptions as in Lemma 4.6 with* R' *sufficiently small there exists a finite number* $N_{\rho'}$ *of curves* $\Gamma_j^{\rho'}$ *such that* $\Gamma_j^{\rho'} \cap A_{R',\rho'} \neq \emptyset$. *We then have*

$$\begin{aligned} \operatorname{supp}(\mu_{\lfloor A_{R',\rho'}}) &= \partial_\star(A^+_{R',\rho'}) \setminus \partial A_{R',\rho'} \\ &= \bigcup_{j=1}^{N_{\rho'}} \Gamma_j^{\rho}. \end{aligned}$$

Proof. As in Lemma 3.2 this is due to the coarea formula and the fact that the curves $\Gamma_i^{\rho'}$ are level curves of the harmonic function H. □

The next result shows that, with R' fixed if we take a larger annulus, then the number of curves in the decomposition of the support of μ is the same. This is due to the geometry of these curves since they are level curves of the harmonic function H.

Lemma 4.9. *Under the same assumptions as in Lemma 4.6 let* $\rho_1' < \rho_2'$ *and* R' *as before small enough. Then using the previous notations we have* $N_{\rho_2'} = N_{\rho_1'}$ *and, up to re-order it holds* $\Gamma_j^{\rho_1'} \subset \Gamma_j^{\rho_2'}$ *for* $j = 1, ..., N_{\rho_1'}$.

Proof. Using the previous notations we have:

$$\operatorname{supp}(\mu_{\lfloor A_{R,\rho_1}}) = \bigcup_{j=1}^{N_{\rho_1}} \Gamma_j^{\rho_1}$$

$$\operatorname{supp}(\mu_{\lfloor A_{R,\rho_2}}) = \bigcup_{j=1}^{N_{\rho_2}} \Gamma_j^{\rho_2}.$$

Besides it holds that $\operatorname{supp}(\mu_{\lfloor A_{R,\rho_2}}) = \operatorname{supp}(\mu_{\lfloor A_{R,\rho_1}}) \cap \overline{A_{R,\rho_2}}$. We thus deduce that

$$\bigcup_{j=1}^{N_{\rho_1}} \Gamma_j^{\rho_1} \subset \bigcup_{j=1}^{N_{\rho_2}} \Gamma_j^{\rho_2}.$$

We also recall that we have the existence of real numbers $(c_j^{\rho_1}), j = 1, ..., N_{\rho_1}$ and $(c_j^{\rho_2}), j = 1, ..., N_{\rho_2}$ such that $\Gamma_j^{\rho_1}$ is exactly one connected component of $\{H = c_j^{\rho_1}\} \cap A_{R,\rho_1}$ and $\Gamma_j^{\rho_2}$ is exactly one connected component of $\{H = c_j^{\rho_2}\} \cap A_{R,\rho_2}$.

Assume that there exists $c_{j_0}^{\rho_1}$ which is different from all the $c_i^{\rho_2}$ for $i = 1, ..., N_{\rho_2}$. Thanks to the maximum principle every connected component of level curves of the harmonic function H which lies in the ball B_R meets the boundary of this ball if R is small enough. We thus obtain that $\Gamma_{j_0}^{\rho_1} \cap A_{R,\rho_2} \neq \emptyset$ and then

$$\Gamma_{j_0}^{\rho_1} \cap A_{R,\rho_2} \subset \operatorname{supp}(\mu_{\lfloor A_{R,\rho_2}}).$$

As a consequence we obtain that $\Gamma_{j_0}^{\rho_1} \cap A_{R,\rho_2} = \Gamma_{i_0}^{\rho_2}$ for some $1 \leq i_0 \leq N_{\rho_2}$. This is a contradiction with our hypothesis on $c_{j_0}^{\rho_1}$. We then have

$$\{c_j^{\rho_1}\}_j = \{c_i^{\rho_2}\}_i.$$

With the same justification we prove that $N_{\rho_1} = N_{\rho_2}$. And then up to reorder we have

$$\Gamma_j^{\rho_1'} \subset \Gamma_j^{\rho_2'} \text{ for } j = 1, ..., N_{\rho_1'}.$$

□

We are now in position to prove:

Lemma 4.10. *Let θ, H be such that* (53) *holds with h which satisfies* (40), (41), (42). *As before we set $B_R^+ = \{z \in B_R; \theta(z) = +1\}$. Then there exists $R > 0$ small enough such that $\mathcal{H}^1(\partial_\star B_R^+ \setminus \partial B_R) < +\infty$ and consequently θ is in $BV(B_R)$.*

Proof. By contradiction if $\mathcal{H}^1(\partial_\star B_R^+ \setminus \partial B_R) = +\infty$ then for all sequence (ρ_n) of real numbers such that $\rho_n \searrow 0$ we have

$$\lim_{n\to+\infty} \mathcal{H}^1(\partial_\star A_{R,\rho_n}^+ \setminus \partial A_{R,\rho_n}) = +\infty. \tag{59}$$

with $A_{R,\rho} = \{z \in \mathbb{C}; \rho < |z| < R\}$ and $A_{R,\rho^+} = A_{R,\rho} \cap B_R^+$. This is due to the fact that

$$\begin{aligned} \partial_\star B_R^+ \setminus \partial B_R &= \bigcup_{n\in\mathbb{N}} \partial_\star B_R^+ \cap A_{R,\rho_n} \\ &= \partial_\star A_{R,\rho_n}^+ \setminus \partial A_{R,\rho_n} \end{aligned}$$

and the union of these sets is increasing. We now use the previous Lemmas 4.6 and 4.9 to obtain that for R small enough there exists an integer N such that for all $n \in \mathbb{N}$ there are N simple connected rectifiable curves $\Gamma_j^{\rho_n}$ and N real numbers c_j such that

$$\partial_\star A_{R,\rho_n}^+ \setminus \partial A_{R,\rho_n} = \bigcup_{j=1}^N \Gamma_j^{\rho_n}$$

and $\Gamma_j^{\rho_n} = \{H = c_j\} \cap A_{R,\rho_n}$. Furthermore we also have $\Gamma_j^{\rho_n} \subset \Gamma_j^{\rho_m}$ if $n > m$. We then obtain

$$\begin{aligned} \mathcal{H}^1\left(\partial_\star B_R^+ \cap A_{R,\rho_n}\right) &\leq \mathcal{H}^1\left(\bigcup_{i=1}^N \{H = c_i\} \cap B_R\right) \\ &\leq \sum_{i=1}^N \mathcal{H}^1\left(\{H = c_i\} \cap B_R\right). \end{aligned}$$

But for R small enough the level curves of H have a finite Hausdorff measure. Thus there exists $M > 0$ such that for all $n \in \mathbb{N}$,

$$\mathcal{H}^1(\partial_\star B_R^+ \cap A_{R,\rho_n}) \leq M.$$

This is a contradiction with (59) and then $\mathcal{H}^1(\partial_\star B_R^+ \setminus \partial B_R) < +\infty$.

Now we prove that $\theta \in BV(B_R)$. We recall that in the proof of Lemma 4.2 we found that

$$\partial_x\theta - i\partial_y\theta = \frac{\Delta h}{g} = \frac{1}{g}\mu$$

in the sense of distributions where $g = \partial_x H - i\partial_y H$. We then have

$$\partial_x\theta - i\partial_y\theta = \frac{1}{|g|^2}\overline{g}\mu = \frac{(\partial_x H + i\partial_y H)\mu}{|\nabla H|^2}$$

thus $\partial_x\theta = \frac{\partial_x H}{|\nabla H|^2}\mu$ and $\partial_y\theta = \frac{\partial_y H}{|\nabla H|^2}\mu$. Now for all $\varphi \in \mathcal{C}_c^1(B_{R'}, \mathbb{R}^2)$ with $|\varphi| \leq 1$

$$\begin{aligned} \int_{B_R} \theta \operatorname{div}\varphi &= -\langle \partial_x\theta, \varphi_1\rangle - \langle \partial_y\theta, \varphi_2\rangle \\ &= -\int_{B_R} \frac{\partial_x H}{|\nabla H|^2}\varphi_1 d\mu + \int_{B_R} \frac{\partial_y H}{|\nabla H|^2}\varphi_2 d\mu. \end{aligned}$$

We now use Lemma 4.4 to say that

$$\mu_{\lfloor B_R} = -2\nabla H \cdot \nu^+_{B_R} \mathcal{H}^1_{\lfloor \partial_\star B_R^+ \setminus \partial B_R}$$

hence

$$\int_{B_R} \theta \operatorname{div} \varphi \ = \ 2\int_{\partial_\star B_R^+ \setminus \partial B_R} \nabla H \cdot \nu_{B_R^+} \frac{\partial_x H \varphi_1}{|\nabla H|^2} d\mathcal{H}^1 - 2\int_{\partial_\star B_R^+ \setminus \partial B_R} \nabla H \cdot \nu_{B_R^+} \frac{\partial_y H \varphi_2}{|\nabla H|^2} d\mathcal{H}^1.$$

We thus deduce, using the fact that $|\frac{\partial_x H}{|\nabla H|^2}| \leq 1$ and $|\frac{\partial_y H}{|\nabla H|^2}| \leq 1$, that

$$|\int_{B_R} \theta \operatorname{div} \varphi| \leq 4\mathcal{H}^1(\partial_\star B_R^+ \setminus \partial B_R) < +\infty$$

for all $\varphi \in \mathcal{C}^1_c(B_R, \mathbb{R}^2)$; $|\varphi| \leq 1$. This proves the claim. □

From this point we have all the ingredients to pursue the proof of Theorem 1.2 as in the previous section.

Proof of Theorem 1.2.

Claim 4.1. *There exist $R > 0$ small enough, a finite number N and N simple, connected, rectifiable curves Γ_j such that*

$$\operatorname{supp}(\mu_{\lfloor_{B_R}}) = \partial_\star B_R^+ \setminus \partial B_R = \bigcup_{j=1}^N \Gamma_j.$$

Furthermore for all $1 \leq j \leq N$ there exists c_j such that Γ_j is exactly a connected component of the level set $\{z \in \mathbb{C}, H(z) = c_j\} \cap B_R$.

Once we know that the function θ defined by (57) is in $BV(B_R)$ for R small enough we can apply the same arguments as in the previous section to prove this claim, it results from an adaptation of Lemmas 3.4, 3.6, 3.7, and Claims 3.1, 3.2.

We can now conclude the proof of Theorem 1.2. The last claim proves that there exist a finite number of Γ_j near $Z_0 := \{z \in B; H(z) = 0\}$. Thus there exists $\eta > 0$ such that $\operatorname{dist}(Z_0, \Gamma_i) > \eta$ for all $j \in \mathbb{N}$ such that Γ_j is not included in Z_0. We then set $V := B(z_0, \frac{\eta}{2})$. Because of the definition of η we can say that

$$\operatorname{supp}(\mu_{\lfloor V}) \subset \{z \in; H(z) = 0\}.$$

We also set as usual $V^+ = \{z \in V; \theta(z) = +1\}$,$V^- = \{z \in V; \theta(z) = -1\}$. We have that

$$\nabla h = +\nabla H, \ \text{ on } V^+, \quad \nabla h = -\nabla H, \ \text{ on } V^-.$$

Note that in V the function θH is continuous since $H = 0$ at the discontinuity points of θ. Then θH is in $H^1(V)$ since H is in H^1. Computing $\nabla(\theta H)$ in the sense of distributions we obtain that $\nabla(\theta H) = \theta \nabla H$. Besides it comes

$$\nabla(h - \theta H) = 0 \text{ in } V.$$

This proves that $h - \theta H$ is constant in V, but evaluating this constant in z_0 we find that

$$h = \theta H, \ \text{ in } V.$$

This concludes the proof of Theorem 1.2.

□

5. Third case: local behavior near a zero of odd order of $\omega_{h_\mu}(z) = (\partial_x h_\mu - i\partial_y h_\mu)^2(z)$

In this section we deal with the case where z_0 is a point in the support of μ and z_0 is a zero of odd order of ω_{h_μ}. This case is the most difficult. Indeed unlike the previous cases we can not find a holomorphic function g such that $(\partial_x h_\mu - i\partial_y h_\mu)^2 = g^2$. We must use *multivalued* holomorphic function to overcome this difficulty. We do not want to discuss here the notion of multivalued function. For us the prototype of multivalued function is $z \mapsto z^{\frac{1}{2}}$. Such a multivalued function is single-valued up to a sign. Indeed given any complex number z different from 0 there exist exactly two complex numbers z_1 and z_2 such that $z_i^2 = z$ for $i = 1, 2$ and $z_1 = -z_2$. In particular $|z^{\frac{1}{2}}| = |z|^{\frac{1}{2}}$ is well defined. We drop the subscript μ during the rest of this section.

Lemma 5.1. *Let h which satisfies* (40), (41), (42). *Let $z_0 \in \Omega$ be a zero of odd order of $\omega_h(z) = (\partial_x h - i\partial_y h)^2(z)$. Then there exist W a neighborhood of z_0, a function $\theta : W \to \{\pm 1\}$ and a function $H : W \to \mathbb{R}$ which satisfies $H = |H_1|$, where H_1 is a multivalued function W such that*

$$\partial_x h(z) - i\partial_y h(z) = \theta(z)(\partial_x H(z) - i\partial_y H(z)) \text{ in } W. \tag{60}$$

Furthermore the function H_1 is such that: there exist an unique integer $n \geq 1$, a small number $r > 0$ and a biholomorphism $\Phi : B(0, r) \to W$ such that $\Phi(0) = z_0$ and

$$H_1 \circ \Phi(z) = Re(z^{n+\frac{1}{2}}), \quad \text{for } z \in B(0, r) \tag{61}$$

Proof. Let z_0 be a zero of odd order of $(\partial_x h - i\partial_y h)^2$. We can find a neighborhood U of z_0, an integer n and a holomorphic function $f_1 : U \to \mathbb{C}$ with $f_1(z_0) \neq 0$ such that

$$(\partial_x h - i\partial_y h)^2 = (z - z_0)^{2n+1} f_1(z).$$

Since $f_1(z_0) \neq 0$, there exists a smaller neighborhood of z_0, still denoted by U and a holomorphic function $\varphi_1 : U \to \mathbb{C}$ such that $\varphi_1^2(z) = f_1(z)$, for $z \in U$.
We then set

$$g(z) = (z - z_0)^{n+\frac{1}{2}} \varphi_1(z), \quad \text{for } z \in U. \tag{62}$$

Like $z \mapsto z^{\frac{1}{2}}$, g is a multi-valued function which is single-valued up to a sign. As in the previous sections we want to take a primitive of the function g. However the fact that g is multivalued introduces a difficulty in this process. But we can show that we can choose a special form of a primitive of g.

Claim 5.1. *There exist a neighborhood U of z_0 and a single-valued holomorphic function $\varphi_2 : U \to \mathbb{C}$ such that $\varphi_2(z) \neq 0$ for all $z \in U$ and*

$$G(z) := (z - z_0)^{n+\frac{3}{2}} \varphi_2(z),$$

satisfies $G'(z) = g(z)$, for all $z \in U$ (where g is defined by (62)*)* .

Proof. Let us assume that such a function φ_2 exists. We then have:

$$\begin{aligned} G'(z) &= [(z - z_0)^{n+\frac{3}{2}} \varphi_2(z)]' \\ &= (n + \frac{3}{2})(z - z_0)^{n+\frac{1}{2}} \varphi_2(z) + (z - z_0)^{n+\frac{3}{2}} \varphi_2'(z) \end{aligned}$$

Since we want $G'(z) = g(z) = (z - z_0)^{n+\frac{1}{2}} \varphi_1(z)$, the function φ_2 must satisfies the following complex ordinary differential equation:

$$(n + \frac{3}{2})(z - z_0)^{n+\frac{1}{2}} \varphi_2(z) + (z - z_0)^{n+\frac{3}{2}} \varphi_2'(z) = (z - z_0)^{n+\frac{1}{2}} \varphi_1(z). \tag{63}$$

In a neighborhood of z_0 we can expand φ_1 in power series

$$\varphi_1(z)=\sum_{k=0}^{+\infty} a_k(z-z_0)^k.$$

Thanks to an expansion in power series we have: $\varphi_2(z)=\sum_{k=0}^{+\infty} b_k(z-z_0)^k$. Using (63) we find that the coefficient b_k must satisfy

$$(n+\frac{3}{2})\sum_{k=0}^{+\infty} b_k(z-z_0)^k+\sum_{k=1}^{+\infty} kb_k(z-z_0)^k=\sum_{k=0}^{+\infty} a_k(z-z_0)^k. \tag{64}$$

Thus we must have

- * for $k=0$: $b_0=\frac{a_0}{n+\frac{3}{2}}$
- * for $k\geq 1$: $b_k=\frac{a_k}{n+\frac{3}{2}+k}$.

We can check that if we set $\varphi_2(z)=\displaystyle\sum_{k=0}^{+\infty}\frac{a_k}{n+3/2+k}(z-z_0)^k$ then $G(z)=(z-z_0)^{n+\frac{3}{2}}\varphi_2(z)$ is a primitive of g. furthermore because $\varphi_(z_0)\neq 0$ we have $a_0\neq 0$ and hence $\varphi_2(z_0)\neq 0$. Thus $\varphi_2(z)\neq 0$ in a neighborhood of z_0 denoted by U. □

We then set

$$H_1(z)=\mathrm{Re}(G(z))$$

and

$$H(z)=|H_1(z)| \text{ for all } z \text{ in } U. \tag{65}$$

Note that H_1 is a multi-valued function which is single-valued up to a sign. The proof of the next claim is very similar to an analogous result for harmonic function (see *e.g.* [12]).

Claim 5.2. *There exist a neighborhood W of z_0, a number $r>0$ and an analytic diffeomorphism $\Phi: B(0,r)\to W$ such that $\Phi(0)=z_0$ and*

$$H_1\circ\Phi(z)=Re(z^{n+\frac{3}{2}}),$$

for all $z\in B(0,r)$.

Proof. We have $H_1(z)=\mathrm{Re}(G(z))=\mathrm{Re}[(z-z_0)^{n+\frac{3}{2}}\varphi_2(z)]$, for all $z\in U$ and $\varphi_2(z_0)\neq 0$ (where U and φ_2 are given by Lemma 5.1). This last property allow us to find a neighborhood of z_0, denoted by W, and a (single-valued) function $\varphi_3: U\to\mathbb{C}$ such that $\varphi_3(z)^{n+\frac{3}{2}}=\varphi_2(z)$ for all $z\in W$. We thus obtain that

$$G(z)=[(z-z_0)\varphi_3(z)]^{n+\frac{3}{2}}.$$

Note also that $\varphi_3(z_0)\neq 0$. We let $k(z)=(z-z_0)\varphi_3(z)$. We have that k is holomorphic, $k(z_0)=0$ and $k'(z_0)\neq 0$. We can thus apply an analytic version of the local inverse theorem to obtain that there exists a neighborhood of z_0, still denoted by W and a number $r>0$ such that $k: W\to B(0,r)$ is an analytic diffeomorphism (or biholomorphism). Now we set $\Phi=k^{-1}$, we have that $k\circ\Phi(z)=z\in B(0,r)$, $\Phi(0)=z_0$ and

$$G\circ\Phi(z)=[k(\Phi(z))]^{n+\frac{3}{2}}=z^{n+\frac{3}{2}}.$$

We then deduce that

$$H_1\circ\Phi(z)=\mathrm{Re}(G\circ\Phi(z))=\mathrm{Re}(z^{n+\frac{3}{2}})$$

for all $z\in B(0,r)$ and the claim is proved. □

One can check that

$$(\partial_x H - i\partial_y H)^2 = \ (\partial_x H_1 - i\partial_y H_1)^2 = g(z)^2 = f(z).$$

We thus deduce that there exists a function $\theta : W \to \{\pm 1\}$ such that

$$(\partial_x h - i\partial_y h) = \theta(\partial_x H - i\partial_y H) \text{ in } W. \tag{66}$$

□

We then set

$$W^+ = \{z \in W; \theta(z) = +1\}, \quad W^- = \{z \in W; \theta(z) = -1\}.$$

Note that the function θ does not play the same role as in the previous section. This is because the function H is not harmonic here. Furthermore H is only lipschitz and not smooth thus we can not use the same argument as in the previous section to prove that θ is in $BV_{loc}(W \setminus \{z_0\})$. Indeed to prove this we used the fact that

$$\theta(z) = \frac{\partial_x h - i\partial_y h}{\partial_x H - i\partial_y H}, \ \forall\ z \in W \setminus \{z_0\}$$

and we differentiated this expression in the sense of distributions, using the Leibniz rule. We can not do the same here since $\partial_x H - i\partial_y H$ is not a smooth function.

For this reason we work in $W \setminus \{z \in U; H(z) = 0\}$. Thanks to Proposition 5.2 we know that this set is an union of $2n+3$ connected disjoint open sets (where n is defined in 5.2). We have

$$W \setminus \{z \in W; H(z) = 0\} = \bigcup_{k=1}^{2n+3} W_k \tag{67}$$

with W_k connected and open and such that $W_k \cap W_j = \emptyset$ if $k \neq j$. In each W_k, H does not vanish and $(\partial_x H - i\partial_y H)$ does not vanish either. We can then find a harmonic single valued function $\tilde{H}_k$ such that

$$|H| = \tilde{H}_k, \ in\ W_k.$$

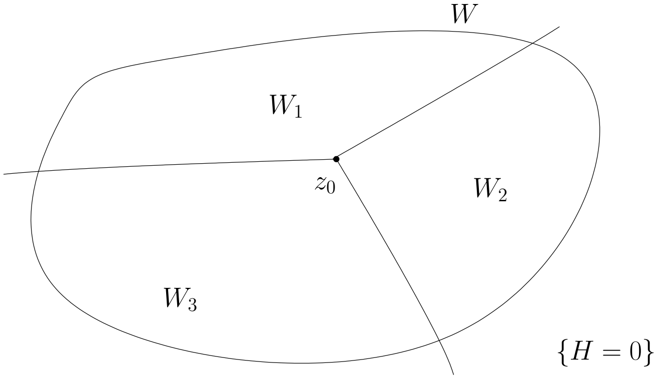

FIGURE 6. Partition of W in disjoint open connected subsets.

In particular $|H| \in \mathcal{C}^\infty(W_k)$ for all $1 \leq k \leq 2n+3$. We are now in position to state that

Claim 5.3. *The function θ is in $BV_{loc}(W_k \setminus \{z_0\})$ for all $1 \leq k \leq 2n+3$.*

The proof of this fact is the same as the proofs of Lemma 3.2 and 4.2 in the previous sections. For $1 \leq k \leq 2n+3$ we set

$$W_k^+ = \{z \in W_k; \theta(z) = +1\}.$$

These sets are sets of locally finite perimeter in W_k. As in the previous sections (see Lemma 3.3) we can obtain

Claim 5.4. *The generalized outer normal* $\nu_{U_k^+}$ *is collinear to* ∇h *and* ∇H, $\|\partial U_k^+\|$-*almost everywhere in* U_k.

We have all the ingredients to repeat the arguments of Sections 3 and 4 in each sub-domains W_k and obtain

Claim 5.5. *For all* $1 \leq k \leq 2n+3$, *there exist* $N_k \in \mathbb{N}$, *and* N_k *simple connected rectifiable curves* Γ_j^k, $1 \leq j \leq 2n+3$ *such that*

$$\partial_\star W_k^+ \setminus \partial W = \bigcup_{j=1}^{N_k} \Gamma_j^k.$$

Furthermore there exist c_j^k *real numbers such that* Γ_j^k *is exactly a connected component of* $\{z \in U; H(z) = c_j^k\}$.

Proof of Theorem 1.4. Let h which satisfies (40), (41), (42). Let W, θ, H be defined by (60) in Lemma 5.1. As before we set

$$W \setminus \{z \in W; H(z) = 0\} = \bigcup_{k=1}^{2n+3} W_k.$$

with W_k open and connected and $W_k \cap W_j = \emptyset$ if $k \neq j$. We also set $W_k^+ = \{z \in W_k; \theta(z) = +1\}$. We use the previous Claim 5.5 and we obtain that for all $1 \leq k \leq 2n+3$, since there are only a finite number of curves Γ_j^k such that $\partial_\star W_k^+ \setminus \partial W = \bigcup_{j=1}^{N_k} \Gamma_j^k$, with the Γ_j^k which are connected component of level curves of H then we can find η_k such that

$$B(z_0, \eta_k) \cap \partial_\star W_k^+ \setminus \partial W \subset \{z \in W; H(z) = 0\}.$$

We then set $\eta := \min_{1 \leq k \leq 2n+3} \eta_k$ and $V := B(z_0, \eta)$. We have that θ is constant in each $V \cap W_k$ since θ is constant in each $B(z_0, \eta_k) \cap W_k$ from the definition of η_k.

We claim that $V^+ = \{z \in V; \theta(z) = +1\}$ is a set of finite perimeter in V. Indeed we have that $\partial V^+ \setminus \partial V \subset \{z \in V; H(z) = 0\}$ (here we use the topological boundary ∂V^+) and $\mathcal{H}^1(\{z \in V; H(z) = 0\}) < +\infty$ from the last point of Lemma 5.1. Then applying Proposition 3.62 of [2] we deduce that V^+ is a set of finite perimeter.

Note that in V the function θH is continuous since $H = 0$ at the discontinuity points of θ. Then θH is in $H^1(V)$ since H is in H^1. Computing $\nabla(\theta H)$ in the sense of distributions we obtain that $\nabla(\theta H) = \theta \nabla H$ and it comes

$$\nabla(h - \theta H) = 0 \text{ in } V.$$

this proves that $h - \theta H$ is constant in V, but evaluating this constant in z_0 we find that

$$h = \theta H \text{ in } V.$$

□

6. Appendix: On the stationary harmonic functions

This appendix is devoted to elementary results on stationary harmonic functions. These results are stated without proof in the introduction of this paper. The original definition of stationary harmonic function is the following:

Definition 6.1. *A function h in $H^1(\Omega)$ is stationary harmonic if for any family of diffeomorphisms ϕ_t of Ω such that $\phi_0 = Id$ we have*

$$\frac{d}{dt}|_{t=0} E(h \circ \phi_t) = 0,$$

where $E(h) = \frac{1}{2}\int_\Omega |\nabla h|^2 dx$ is the Dirichlet energy.

As shown by the following proposition we used an equivalent characterization.

Proposition 6.1. *A function h is stationary harmonic if and only if* $\operatorname{div} T_h = 0$ *in the sense of distributions, where*

$$T_h = \begin{pmatrix} \frac{1}{2}\left[(\partial_y h)^2 - (\partial_x h)^2\right] & -\partial_x h \partial_y h \\ -\partial_x h \partial_y h & \frac{1}{2}\left[(\partial_x h)^2 - (\partial_y h)^2\right]. \end{pmatrix}$$

Proof. We first note that $\operatorname{div}(T_h) = 0$ in the sense of distributions if and only if

$$\int_\Omega \langle T_h, D\eta \rangle = 0, \quad \forall \eta \in \mathcal{C}_c^\infty(\Omega, \mathbb{R}^2),$$

where $D\eta$ denotes the differential of η (which is a 2×2 matrix) and $\langle A, B\rangle = \operatorname{tr}({}^t AB)$ denotes the inner product of two matrices. Let $\phi_t(x) = x + t\eta(x)$ with $\eta \in \mathcal{C}_c^\infty(\Omega, \mathbb{R}^2)$, if t is small enough ϕ_t is a diffeomorphism. Let $h_t := h \circ \phi_t$, we have

$$\nabla h_t(x) = (I + tD\eta(x)).\nabla h(x + t\eta(x))$$

$$|\nabla h_t(x)|^2 = |\nabla h(x + t\eta(x))|^2 + 2t\langle \nabla h(x + t\eta(x)), [D\eta(x).\nabla h(x + t\eta(x))]\rangle + o(t)$$

Then

$$\begin{aligned} \frac{1}{2}\int_\Omega |\nabla h_t(x)|^2 dx &= \frac{1}{2}\int_\Omega |\nabla h(x + t\eta(x))|^2 dx + \\ &+ t\int_\Omega \langle \nabla h(x + t\eta(x)), [D\eta(x).\nabla h(x + t\eta(x))]\rangle dx + o(t). \end{aligned}$$

We can make the following change of variables $y = x + t\eta(x) \Leftrightarrow x = y - t\eta(x) \Rightarrow x = y - t\eta(y) + o(t)$ (the last implication holds because $\eta(x) = \eta(y) + o(1)$ when t goes to 0). We also have

$$\det\left[D(y - t\eta(y) + o(t))\right] = \det(I - D\eta + o(t)) = 1 - t\operatorname{tr} D\eta + o(t)$$

because $\det(I + tA) = 1 + t\operatorname{tr}(A) + o(t)$. Then

$$\begin{aligned} E(h_t) &= \frac{1}{2}\int_\Omega |\nabla h(y)|^2 dy - \frac{t}{2}\int_\Omega |\nabla h(y)|^2 \operatorname{tr} D\eta(y) dy + \\ &+ t\int_\Omega \langle \nabla h(y), [D\eta(y)\nabla h(y)]\rangle dy + o(t). \end{aligned}$$

Hence

$$\frac{d}{dt}|_{|t=0} E(h_t) = 0$$

is equivalent to

$$\int_\Omega [-\frac{1}{2}|\nabla h(y)|^2 \operatorname{tr} D\eta(y) + \langle \nabla h(y), [D\eta(y).\nabla h(y)]\rangle dy = 0.$$

But

$$\frac{1}{2}|\nabla h(y)|^2 \operatorname{tr} D\eta(y) = \langle \frac{1}{2}|\nabla h(y)|^2 I, D\eta(y)\rangle$$

and

$$\langle \nabla h(y), D\eta(y)\nabla h(y)\rangle = \langle \nabla h(y)^t \nabla h(y), D\eta(y)\rangle$$

with $\nabla h(y)^t\nabla h(y) = \begin{pmatrix} (\partial_x h)^2 & \partial_x h \partial_y h \\ \partial_y h \partial_x h & (\partial_y h)^2 \end{pmatrix}$. We can then conclude that

$$\frac{d}{dt}|_{|t=0} E(h_t) = 0 \Leftrightarrow \int_\Omega < T_h, D\eta >= 0$$

which is equivalent to $\operatorname{div}(T_h) = 0$ with $T_h = \nabla h^t \nabla h - \frac{1}{2}|\nabla h|^2 I$. □

The equation (5) can also be interpreted in terms of holomorphic functions

Proposition 6.2. *The condition* $\operatorname{div}(T_h) = 0$ *is equivalent to* $\omega_h := |\partial_x h|^2 - |\partial_y h|^2 - 2i\partial_x h \partial_y h$ *is holomorphic in* Ω.

Proof.

$$\operatorname{div}(T_h) = 0 \Leftrightarrow \left\{ \begin{array}{rcl} \partial_x(\partial_x h^2 - \partial_y h^2) & = & \partial_y(-2\partial_x \partial_y h) \\ \partial_y(\partial_x h^2 - \partial_y h^2) & = & -\partial_x(-2\partial_x\partial_y h). \end{array} \right.$$

These are the Cauchy-Riemann equations for ω_h written in the sense of distributions. We can rewrite them as $\partial_{\bar z}\omega_h = 0$ where $\partial_{\bar z} = \frac{1}{2}(\partial_x + i\partial_y)$. The operator $\partial_{\bar z}$ is elliptic and hence the elliptic regularity theory shows that ω_h is smooth and then holomorphic because it satisfies the Cauchy-Riemann equations. □

Proposition 6.3. *If h is harmonic in Ω then h is stationary harmonic in Ω.*

Proof. Assume that $\Delta h = 0$ in Ω. Recall that $\Delta v = 4\partial_{\bar z}\partial_z v$ and let us compute

$$\begin{array}{rcccl} \partial_{\bar z}\omega_h & = & 4\partial_{\bar z}[\partial_z h]^2 & = & 8\partial_z h \partial_{\bar z}\partial_z h \\ & = & 8\partial_z h \Delta h & = & 0. \end{array}$$

Hence $\partial_{\bar z}\omega_h(z) = 0$, that is ω_h is holomorphic.

□

The converse of the previous proposition is not true. However if h is a stationary harmonic functions which statisfies the hypothesis (3), (4), (5) with $\mu \in L^p$, $p > 1$, then, using the same methods as in [11] Chapter 13, one can show that h is harmonic.

Proposition 6.4. *If μ is in $L^p(\Omega)$ for some $p > 1$ and satisfies (5),(4) then $\mu = 0$.*

Proof. Let μ be in $L^p(\Omega)$ for some $p > 1$ and such that $\operatorname{div}(T_\mu) = 0$ and $\Delta h_\mu = \mu$. Let ρ_n be a regularizing kernel, we set $\mu_n := \mu * \rho_n$, $h_n := h_\mu * \rho_n$ and

$$T_n := \frac{1}{2}\begin{pmatrix} \partial_y h_n^2 - \partial_x h_n^2 & -2\partial_x h_n \partial_y h_n \\ -2\partial_x h_n \partial_y h_n & \partial_y h_n^2 - \partial_x h_n^2 \end{pmatrix}.$$

One has $\mu_n \to \mu$ in $L^p(\Omega)$, and because ∇h_μ is in $L^\infty_{loc}(\Omega)$ one also has $\nabla h_n \to \nabla h_\mu$ in $L^q_{loc}(\Omega)$, for all $q \in [1, +\infty[$. Then

$$\mu_n \nabla h_n \to \mu \nabla h_\mu, \text{ in } L^1_{loc}(\Omega)$$

and

$$T_n \to T_\mu, \text{ in } L^1_{loc}(\Omega).$$

The last equation implies that $\operatorname{div}(T_n) \to \operatorname{div}(T_\mu) = 0$ and $\mu_n\nabla h_n \to \mu\nabla h_\mu$ in the sense of distributions. However $\operatorname{div}(T_n) = -\Delta h_n \nabla h_n = \mu_n \nabla h_n$ thus $\mu\nabla h_\mu = \lim_{n\to+\infty} \operatorname{div}(T_n) = 0$ in $L^1_{loc}(\Omega)$ and almost everywhere. From a property of Sobolev functions we have $\Delta h_\mu = 0$ a.e. on the set $F = \{\nabla h_\mu = 0\}$, thus $\mu = 0$ a.e. on F and $\mu = 0$ on $\Omega \setminus F$ hence $\mu = 0$ on Ω. $\square$

Acknowledgments. I would like to thank my Ph.D. advisor E.Sandier for his support and useful comments on this subject. I would also like to thank J.M. Delort and S.Masnou for interesting discussions on this work, and X.Lamy for valuable comments which helped to improve the presentation of the paper.
